Professor HUGHES's estate has been valued at £473,034 9*s.* 3*d.*, including personalty of the net value of £472,704 15*s.* 4*d.* After making provision for his family and certain bequests to friends he directs that his entire personal estate (including bonds, shares, stocks, and securities at the London Joint Stock Bank) shall constitute a trust fund, to be called the "David E. Hughes Hospital Trust Fund," of which the first trustees shall be the treasurers of the Middlesex Hospital, the London Hospital, King's College Hospital, and Charing-cross Hospital respectively. Out of this fund they are to pay certain annuities. One-half of the remaining income is to accumulate during 21 years and is to be added to the principal, while the remaining one-half of the income is to be distributed in equal shares amongst the said four hospitals, provided they keep in use continuously 100 beds for the use of patients. At the expiration of the 21 years the whole income of the trust is to be so applied. If any of the treasurers refuse to accept the office of trustee their hospitals are to be treated as decayed hospitals. The sum at present available for the Hughes Hospital Fund seems likely to be between £300,000 and £350,000; eventually it will be over £400,000. It was Professor HUGHES's earnest desire that after the period of 21 years the four hospitals should voluntarily add to their respective funds as capital one third of their income from his bequest, and the encouragement to thrift thus held out is worthy of all approbation The testator evidently did not believe in the policy sometimes forced upon hospital authorities, and sometimes, we fear, recklessly pursued, of living on capital and trusting to urgent appeals or financial good luck to make up the deficits

The intelligent munificence of Professor HUGHES will do good beyond its designs Much of the hospital charity which we see is of a halting order The sums cast into the treasury are shillings and odd guineas—widows mites without the saving grace of the widows' penury But here is something like an adequate conception of the work of hospitals and of what should be the scale of gifts to them by wealthy people A few such gifts every year would give new zest to hospital committees and would enlarge the area of hospital relief from which at present thousands of proper objects are excluded We have often said in discussing the scantiness of hospital funds that we want a few men like GUY to follow a grand example Here is a gift like that of GUY, GUY gave for the building of his hospital, which has had such a glorious history, £18,793 and for its endowment £219,499—in all £238 292—and after nearly 200 years his generosity remains a source of healing and of hope to the sick poor of London We are now praising a similar bequest and we commend it cordially for imitation to those who have the means in this wealthier age when the Chancellor of the Exchequer can reckon on the estates of several millionaires each year as a source of national income That such gifts as those of GUY and HUGHES are not more frequent is a matter which may excite surprise The explanation must be found partly in the defective altruism of an age which is tempted by its very wealth to be selfish, indulgent, and luxurious

◆

THE annual report of the Medical Defence Union demonstrates most clearly the excellent work which has been done in the interests of the members of that Union by those entrusted with office The members of the council, under the presidency of Dr W S A GRIFFITH, meet once a month to consider the applications for assistance or advice that have been received, but so large is the amount of business which has to be conducted that a meeting of the Executive Committee has also generally to be summoned to deal with those matters which the council has been unable to dispose of owing to pressure of time The number of members now upon the register amounts to 4465, 449 new members having been elected during the year The financial stability of the Union is ensured by a guarantee fund of £6375 8s, which is available if called up under articles of association

The report consists mainly of two sections one being drawn up by the secretary Dr A G BATEMAN, and the other by the solicitor, Mr W E HEMPSON The aim of the management has always been "defence," and no just expense is spared in the conduct of legal cases brought into court The Union, therefore has spent very little money this year in the prosecution of quacks It was decided, naturally enough perhaps that the subscriptions of members should not be utilised for the benefit of those who are not subscribers, but that the funds should be husbanded for the individual defence of those who are wise enough to "insure" The few instances of such prosecutions mentioned in the solicitor's report are cases in which the council was requested to act by a large body of members living in the district in which the quack ' practised, and in these prosecutions the work done was practically the defence of members of the Union against illegal competition The council is of opinion that until the number of subscribers is much increased and a new Medical Act with a more comprehensive and intelligible penal section is brought in and passed as the law of the country, the prosecution of unqualified practitioners must be left almost entirely to the General Medical Council This expression of opinion was prompted by the solicitor's report for 1898, in which he advised that in view of the indefinite and unascertained basis of the law the Union should not undertake any further prosecutions under the Medical Acts The law as expounded by the magistrates lends but little encouragement to efforts made by the Union and other bodies to suppress unqualified practice, and a conviction can rarely be obtained even if the evidence be of the clearest possible description The council of the Union therefore was practically forced to come to the conclusion not to initiate further action until the Medical Acts shall have been altered Meanwhile a large number of medical men have had reason to be thankful that they are members of the society A perusal of the report forms instructive reading, and those members of the profession who have not read it will have little idea of the number, the scope, and the variety of cases which have been brought under the notice of the council The great majority of applications of all kinds from members can be satisfactorily dealt with by the council, but many are referred to the solicitor His report deals with 120 cases of which 36 relate to the suppression of libels and slanders published and circulated regarding members, 19 relate to the defence of members in actions instituted against them for malpraxis, 42 relate to actions undertaken or defended in a miscellaneous variety of matters in which members needed legal advice and assistance and the remaining 23 involved questions having to do with the suppression of unqualified practice and the prosecution of unqualified practitioners It will thus be observed that the defence of members against libel and slander formed a large and important item of the year's work, and we believe that it is in this connexion that the benefits which members enjoy are felt more than in any other way We have already referred to this aspect of the work of this and kindred societies[1] Mr HEMPSON in his report truly points out that a professional man's reputation is everything to him and unless he is enabled to maintain it unsullied his position in his profession is bound to suffer It is unfortunately true that a medical man is particularly open to attacks on his character, and apart from the relief which the membership of such a society accords him from personal expenses and anxieties, he has the knowledge that a solid body of professional brethren are at his back and supporting his interests In connexion with such matters other remarks of Mr HEMPSON are significant. In our article above referred to we suggested that although an evil-disposed person is willing to enter the law courts against a single individual, he will hesitate if he knows that his intended victim is supported by a powerful society, one of whose aims it is to defend its members when they are attacked. That this principle is becoming more generally recognised as the Union increases in strength is shown by Mr. Hempson's statement that with an increased membership of something like 500 new members over that of the year 1898 it has been found necessary to place in his hands for legal advice and adjustment 120 cases as compared with 138 cases in the year 1898.' There is force in Mr. Hempson's contention that this statement should carry conviction to the minds of members of the medical profession as to the practical utility of the work of the Union in securing to its members far less risk of being involved in litigation than is incurred by those members of the profession who have not availed themselves of the protection which membership of such an organisation affords. There is a further fact upon which the council lays very proper emphasis—that an increasing number of threatened actions against the members are nipped in the bud, it being sufficient for the member to intimate to the solicitors of the attacking party that he has placed his case in the hands of the Medical Defence Union and that its solicitor is prepared to go on with it for the action to be immediately abandoned.

---

[1] THE LANCET August 12th 1899 p 417

We have not space to comment on the numerous cases which are related in the report. But we gladly avail ourselves of the opportunity of expressing our interest in the useful work which is well done by the society. In view of the steady and successful progress of this and kindred societies there is some reason to hope that our profession is at length realising that in union there is strength.

In the Probate, Admiralty, and Divorce Division of the High Court of Justice, before the President, Sir F. Jeune, the case of Crook v. Crook and Horrocks was brought to a termination last week. This was a petition brought by Dr. H. E. Crook, formerly practising at Margate, praying for dissolution of marriage on the ground of the alleged misconduct of his wife with the co-respondent. The details of the case are known to most of our readers, but are set out with more circumstance in an article from a legal correspondent, which will be found on p. 793. The jury found that Dr. Horrocks had not committed adultery with the respondent, but were unable to agree with regard to Mrs. Crook. The evidence tendered during the hearing pourtrayed at once romance and tragedy, and the bitterness of the cup held to Dr. Horrocks was intensified by the fact that he had in his professional capacity attended Mrs. Crook and that Dr. Crook was formerly his pupil. It appears that Dr. Horrocks was consulted by Dr. Crook for some ailment incidental to her sex from which his wife suffered. Of course, the services of Dr. Horrocks were gratuitous. At a later period Mrs. Crook bore a child to which she was devotedly attached, and in fact, according to her husband's statement, she gave up her whole life to its care. Subsequently to this event the petitioner, who had never had reason to suspect his wife's chastity, was induced to visit a female palmist, to whose vaticinations he appears to have turned a not altogether deaf ear. This reader of men's minds by their hands averred to her client that he ought to have been a barrister instead of a medical man, and as a matter of fact Dr. Crook was called to the bar. She told him that he would undertake a voyage, which Dr. Crook, in answer to counsel, said was not unlikely. There can be little doubt that the petitioner was much impressed by his communings with the palmist. He told his wife of his strange experience and gave her the address of the woman. Eventually Mrs. Crook also consulted her, and according to her evidence was told that she would be separated from her husband, "but not by death," and that she had broken her marriage vow.

To what extent the foreboding thus induced was likely to prey on Mrs. Crook's mind—whether it was able to fashion a phantasy of guilt to be transmuted into a "fixed idea"—we do not deem it prudent to decide, seeing that the case may still be considered *sub judice* so far as the respondent is concerned; but we may safely assert that the prophecies were not calculated to have a bracing effect upon any brain—much less would they act beneficially on one in unstable equilibrium. As time went on Mrs. Crook asked her husband what was meant by "adultery," then confessed herself guilty of the offence, and named Dr. Horrocks as her co-partner in guilt. She made a written statement of her infidelity, which was afterwards repeated and amplified. Beyond all reasonable doubt it may be accepted that, truly or falsely spoken, Mrs. Crook at the time believed in her own guilt. From the testimony of Dr. Horrocks on oath it transpired that the first intimation of the charge against him was a letter from the petitioner's solicitor. Further, that from the day that he received that letter until the hearing of the case he had no communication with either Dr. Crook or Mrs. Crook. Dr. G. H. Savage and Dr. G. E. Herman were called as expert witnesses. In the former's opinion Mrs. Crook's confession was the outcome of "nervous instability," in fact, on this point she was "under a delusion." Dr. Herman believed that the respondent's present statement was true and that her confession was false. To obtain a judgment against a co-respondent the law requires that the evidence of adultery, if tendered by one of the parties, must have corroboration. And rightly so, for otherwise the innocent would be at the mercy of the malicious accuser. In the case under consideration there was no such corroboration in any shape or form. There was simply the confession of the respondent, which was afterwards negatived by her. She did not deny that she made the confession; nay, more, she testified in court that she believed it when she made it. Dr. Crook had no grounds to suspect his wife's infidelity before she informed him of it, and Dr. Horrocks said that when she consulted him she behaved as a prudent and chaste woman.

Dr. Horrocks's counsel at the close of the petitioner's case raised the question of the dismissal of the co-respondent from the suit, there being no corroborative evidence. We take it that this was but an adroit move, for he instantly fell in with the judge's interposition and put his client in the witness-box, when a complete denial was given to every word of Mrs Crook's story. From first to last in this unhappy cause there was not a tittle of testimony implicating Dr. HORROCKS save the confession of the respondent which she subsequently declared to be false. The case against him was dismissed, the jury having found that he had not committed adultery, but the fact that they could not agree about the innocence of the respondent must be extremely galling to him. Dr. HORROCKS has our sincere sympathy. He has undergone great suffering, but he will derive consolation from the fact that his profession and the public will accord him the full meed of untarnished honour. We trust that many of our readers will hasten to give practical proof of their feelings by responding to the movement started in our columns by Dr. WILLIAM DUNCAN's letter, to which we refer them. One fact came out at the trial of the highest significance to the medical profession—viz., that Dr. HORROCKS, as was *frequently* his *practice when attending* female patients, saw Mrs. CROOK alone. We are aware that this course is pursued by many practitioners, and there are difficulties in the way of entirely superseding it. One patient may have a highly confidential statement to make to her medical man; whilst another, without sufficient grounds perhaps, prefers not to divulge, even to a friend, the nature of her ailment. Nevertheless, we are of opinion that whenever possible a medical man should insist on the presence of a third person when called upon to examine a female patient.

Annotations.

"Ne quid nimis"

THE COLONIES AND THE WAR.

IF the present war has called for great sacrifices in blood and treasure and has carried much suffering and sorrow into many households it has also had its consolations, if not its compensations, in that it has overthrown the social class barriers that tend to separate us one from another by the flood of common feeling and sympathy it has called forth. Some unexpected advantages have already sprung out of the war and these will probably be followed by others of which we now have but little conception. One of the results which promptly followed the publication of the ultimatum on the part of the Boer Government was the grand way in which our colonies rallied to the aid of the mother country and vied with one another in proffering their services on her behalf. The nation had every reason to regard their action with unfeigned pride and satisfaction and we are glad to say it has been almost universally recognised in terms of high appreciation not only by the press of the country, but also as a matter for congratulation among all sorts and conditions of men. The several parts of the empire have become unified and welded together by the present war into an organic whole The bonds of union are those of a common kinship in feeling and interest which have been sealed by mutual services and sacrifices on the battle fields of South Africa While this is all as it should be we should greatly regret if our indebtedness to our various colonies for the great services they have rendered in the aid and succour of the sick and wounded were allowed to pass unnoticed and were not as fully appreciated in fitting terms as they deserve to be. In addition to the splendid contingents of first class fighting men that have come from so many distant parts of the empire in order to stand beside our troops in South Africa, where they have already played such a prominent and worthy part, the medical service of the army in the field has received great accessions to its strength from the same sources. Canada, Australia, New South Wales, New Zealand, and Ceylon have sent very efficient medical aid and India has contributed an invaluable body of dhoolie bearers. In connexion with one of the recent engagements of the force fighting its way to Bloemfontein we read that the New South Wales ambulances, under Major Fiaschi, were out all night collecting the wounded. From the colonies there have come hospitals, hospital ships, and hospital *matériel* of all kinds, supplemented by a highly qualified medical *personnel* who have done very hard and excellent work during the campaign, often under circumstances of danger and more or less hardship to themselves. They were not, to borrow a phrase from Mr. Wyndham, fulfilling a contract but obeying the instincts of an Imperial race. We had the gratification of announcing last week that Sir Thomas Fitz-Gerald, F R C S. Irel., senior surgeon to the Melbourne Hospital, was proceeding to the scene of war. Sir Thomas Fitz-Gerald enjoys a high reputation for his professional attainments and operative skill and he temporarily relinquishes a large and lucrative practice in order to place his services at the disposal of the army in South Africa, and he is only a notable example, we are proud to say, of that patriotic spirit which has been so commonly manifested by members of the medical profession throughout the colonies We believe that we are right in saying that Sir Thomas FitzGerald will only be renewing an old acquaintance with the Army Medical Service, for a commission in which he was long ago a successful competitor, but had to leave Netley owing to an acute attack of illness, to recover from the effects of which he went to Australia, and happily did so. What the Royal Army Medical Corps lost the capital of Australia gained, for he has there had a most distinguished career as a hospital surgeon.

THE NATIONAL ASSOCIATION FOR THE PREVENTION OF CONSUMPTION.

THE first general meeting of members of this association was held on March 13th at the Royal Medical and Chirurgical Society's rooms, 20, Hanover-square, W., when there was a fair attendance. The Earl of Derby, who presided, said the first year of the society's existence had certainly been attended with very successful progress. He abstained from commenting on the report, which had been distributed among those present, but alluded to the fact that since the first meeting last year a contributory meeting of those who intended to take part in the International Congress which it was proposed to hold in 1901 had taken place. The congress at Berlin was attended with so much success that it was thought it would be useful to bring together again the great medical authorities and lights of science from various parts of Europe and the rest of the world. On that occasion the Prince of Wales, with his accustomed readiness, had accepted the office of President Lord Spencer, in a very short speech, moved the adoption of the report. The subject, he said, was one on which they all felt the very deepest interest, as it concerned the health of the population of England. Dr L H Bryson seconded the adoption of the report. He alluded to the narration by Lord Strathcona of a case of a patient suffering from phthisis who was rejected by all the insurance offices of Canada but who after a sojourn in the Rocky Mountains was accepted as a first class life. They could not hope to equal that in England, but he trusted that the knowledge which the association was spreading would result in a modification of the hard-and-fast rules binding insurance offices which were based on the knowledge of 30 or 40 years ago It was not too much to hope that the big life assurance offices, which were becoming symptoms were present. Referring to the question of female nurses he and those on the spot were fully convinced that they were out of place at the front. There were 1800 male nurses of a very high order at the front. A field hospital to be of any use must be perfectly mobile, and this was impossible with female nurses. He spoke very highly of the new departure to provide civil consulting surgeons of eminence. They were not only of the greatest use in the treatment of cases, but were also towers of strength in defence from adverse criticism. The toast of the President was proposed by Sir William Broadbent, and the speeches were interspersed with some excellent music by Dr. S. Henning Belfrage, Mr. C. Preston Wynne, Dr. Campbell Pope, and Dr. Frederick Roberts.

INQUESTS HELD BY THE CORONER OF LIVERPOOL IN 1899.

THE total number of cases of death reported to, and investigated by, the coroner of Liverpool during the year 1899 amounted to 1824. Inquest was deemed unnecessary in 782 instances. 1042 inquests were held, involving the deaths of 636 males and 406 females. Of these 78 were male infants (legitimate) and 77 were female infants (legitimate), under one year. There were 54 males (legitimate) and 64 females (legitimate) of one year and under seven years. Of illegitimate infants under one year there were four males and three females. Of children of seven years and under 16 years there were 39 males and 26 females Of youths of 16 years and under 25 years there were 46 males and 13 females. There were 331 male adults, and 156 female adults of 25 years and under 60 years. 84 males and 67 females were aged 60 years and upwards. Post-mortem examinations were made by order of the coroner in 93 cases. The verdicts of the juries comprised: murder, five females and two males; manslaughter, two males and two females; suicide while insane, 41 males and 10 females; accidental death, 260 males and 179 females; suffocated while in bed with parents, 72 male infants and 64 female infants; found drowned, 16 males and three females; excessive drinking, 144 males and 98 females; want, cold, and exposure, five males and four females; want of attention at birth, three males and three females; natural causes, 73 males and 35 females; injuries, cause unknown, 15 males; stillborn, three males and three females. Inquests were held on the bodies of five newly-born male infants and four newly-born female infants.

TYPHOID FEVER CAUSED BY CELERY.

TYPHOID fever has been attributed to many causes but probably the most novel one is that which is mentioned in a report published by the Springfield *Republican* of Dec. 14th, 1899, on an outbreak of the disease which occurred recently in the Insane Asylum, Northampton, Massachusetts, U S A. This report showed the disease to have been originated and spread by means of celery. It appears that up to Sept. 9th, 1899, the institution had been singularly free from typhoid fever, there having been only four cases in 10 years. But on and after that date cases occurred with alarming frequency, so much so that in about two weeks 40 inmates were stricken with the malady which, moreover, exhibited no signs of abating. Accordingly the services of Dr. Morse of the Massachusetts State Board of Health were requisitioned, and he was requested to make an investigation. The fact was then disclosed that patients, nurses, farm help, and kitchen help were affected, and, further, that the only patients attacked were those who paid for their care at the institution. Therefore it seemed probable that the cause of the epidemic was due to some article of food of which the patients, nurses, and servants partook and in which the non-paying patients had no share. The discovery was made that the paying patients were sometimes supplied with extra articles of food such as fruit and vegetables. At the time of the epidemic they received celery raised on the farm. This vegetable was ultimately decided to be the cause of the disease, and investigations were set on foot thoroughly to probe this theory. It happened that the sewage after being filtered was spread on the celery beds, and owing to the methods used in cultivating celery by banking the stalks of the plant with earth the vegetable provided a very favourable medium for the transmission of the disease. Celery was first used at the Massachusetts Asylum in August and became quite a common article of diet for the paying patients, the nurses, the house help, and the farm help. The most significant fact of all, however, is that one of the farm servants, not realising the danger of eating celery and disregarding the injunctions forbidding its use, ate some, and quickly contracted typhoid fever. After orders had been given to stop the further consumption of celery the epidemic immediately subsided.

"A QUESTION OF LUNACY FEES"

IN THE LANCET of Dec. 23rd, 1899, there appeared a letter under the above heading from Mr. J. L. A. Hope, M.R C S. Eng., regarding the behaviour of the Chertsey Guardians as to payment of fees for certifying lunatics. Mr. Hope is not the parish medical officer, but was asked in a private capacity by the relieving officer to attend at the workhouse and certify seven lunatics. He certified the cases and was offered half a guinea per case by the guardians. This sum he would not accept and demanded one guinea per case. The guardians refused, telling Mr. Hope that he had his remedy. The matter came up at a meeting of the board of guardians held on Feb. 6th, when a letter from Mr. Hope's solicitor was read informing the board that his client had instructed him to take proceedings against the board unless they paid seven guineas The clerk to the board said that the justices had certified for the amount claimed upon the certificate. The board determined to fight the case. They maintain that the law directs the guardians to pay the medical man "such reasonable remuneration as they shall think fit." Mr. Hope's legal advisers rely upon the amount certified on the certificates by the justices. So far as we know the matter is left entirely in the hands of the justices who are empowered to direct the guardians to pay such fee as they, the justices, shall think fit. The question, however, now rests in the hands of the judge who is to hear the case.

INTOXICATION FROM THE USE OF ESERINE DROPS.

THE use of eserine drops in ophthalmic practice is not as a rule attended by any inconvenience. In a recent work by Professor Cohn of Breslau it is stated that their prolonged use does not produce any symptoms. He only knew of one case: in that, spasms of the orbicularis palpebrarum and slight headache had resulted. At the meeting of the Société Médicale des Hôpitaux of Paris on Jan. 19th M. Roubinovitch related the following case. A healthy old man, aged 80 years, had chronic bilateral glaucoma with cupping of the discs and contraction of the visual fields. During three years two drops of a half per cent. solution of sulphate of eserine were instilled twice a day into each eye. For eight or ten months peculiar symptoms had followed each instillation. Sometimes the patient became drowsy and passed into a state of sleep with dreaming; sometimes he remained awake but seemed to lose a correct perception of his surroundings; occasionally attacks of vertigo occurred. The case was then investigated. Before instillation the rectal temperature was 97·7°F. and the pulse was 80 and regular.

Ten minutes after the instillation of four drops of the solution (representing about a milligramme of eserine) the temperature had risen $\frac{2}{5}$° and the pulse-rate had increased by 12 beats in the minute 35 minutes after instillation the temperature had fallen $\frac{9}{10}$°, the pulse had returned to 80, but the tension was increased. On auscultation intermittent action of the heart was found The patient was semi-conscious and had intellectual and sensory troubles. He insisted that he was tied to the ground with his arms suspended in the air, then he declared that he saw a hand in the air suspended before him opening and shutting the fingers. At the same time tonic jerks manifested themselves in the limbs. Three-quarters of an hour after instillation he slept with quasi-stertorous breathing. He awoke after about an hour still having illusions. He had arterio sclerosis and polyuria and, it was thought, a slight degree of granular kidney. Possibly defective elimination by the kidneys was the cause of the production of toxic symptoms by such a small quantity of eserine.

ACTION FOR MALPRAXIS AGAINST AN UNQUALIFIED MAN.

A CASE of some interest has recently been heard at the Brompton County Court in which the plaintiff claimed damages to the amount of £50 from the Sloane Pharmacy Stores, Limited, and also against one Rupert Albert Fyson, an assistant, for the removal of a wrong tooth. The plaintiff stated that the manager of the stores informed her that Fyson was a properly qualified dentist, and on the strength of that statement she had consulted him about a right lower molar tooth which was causing her pain Instead of removing this tooth he applied his forceps to a porcelain crown fixed on the root of an adjacent pre molar, broke the porcelain, and left the pin standing which held the crown on the root. In his evidence the defendant said he was not a registered dentist but had studied dentistry and practised the operation of extraction for about 11 years. He maintained that the fracture of the porcelain crown was due to the struggling of the patient. Expert evidence was called on both sides and the plaintiff eventually obtained damages of £10. This case is another glaring example of the insufficient manner in which the public are protected from unqualified men If the statement contained in the shorthand writer's report is correct, that the manager of the stores stated that Fyson was qualified, then the man was guilty of untruthfulness and should be held to be responsible for the statement

WHITE AND DARK MEATS IN MEDICAL DIETETICS

IN a series of articles recently published[1] Dr. Offer and Dr. Rosenquist deal with the opinion which has been generally accepted by many that white meats are more suitable as a dietary, owing to greater digestibility and the presence of less uric acid and nitrogenous extractives This popular belief has much to answer for in view of the fact that white meats are so generally prescribed for patients who are the subjects of gouty, renal, and allied troubles in particular. The analyses made by Dr. Offer and Dr. Rosenquist show that while the white meats such as poultry and fish do in certain cases—e g , fish and fresh venison—contain less extractives and nitrogenous derivatives, the average amount does not appreciably differ in the white and dark meats—e g , poultry, veal, beef, pork, mutton, &c.—to make either preferable. They point out that the only way of limiting the ingestion of these deleterious extractive and nitrogenous substances is by diminishing the amount of meat taken rather than by forbidding dark meats. They also assert that among the extractives present in meat the most important ones, such as sarcolactic acid and butyric acid, are by no means harmful if taken in small quantities as is ordinarily done, and the same holds good as regards the other organic extractives which are nitrogenous. The bad results which accrue from excessive meat-eating can be neutralised by diminishing the quantity of meat and increasing the amount of vegetables consumed during meals, and in this way disorders and ailments due to excess of uric acid in the blood may be gradually ameliorated. The practice of eating three heavy meat meals a day should be discouraged on the same grounds.

THREE GREAT METEOROLOGISTS.

WITHIN the short space of one week the Royal Meteorological Society has lost three of its most distinguished members, two of whom had filled the office of President. The Presidents were Dr. William Marcet, F.R S., who died on March 4th and who filled the chair (as we note in a fuller notice of his career which will be found in another column) during the term of office 1888–1889, and Mr G J. Symons, F.R S , who was President in 1880–1881. He was elected President a second time in 1900, but illness prevented him re-assuming office and he died on March 10th. The third meteorologist was Mr. E. J. Lowe, F.R S , who also died on March 10th. Dr. Marcet was principally interested in climatology, Mr. Symons's chief work was concerned with rainfall, and Mr. Lowe continued daily meteorological observations, it is said, without a break during nearly 60 years. All were Fellows of the Royal Society.

THE CONSUMPTION SANATORIA OF SCOTLAND.

THE Orphan Homes of Scotland and Consumption Sanatoria of Scotland form at the present time a group of 58 buildings on an extensive site near Bridge of Weir, a country place in Renfrewshire within easy access of Glasgow and Greenock The orphanages owe their origin, now many years ago, to the philanthropy of Mr. William Quarrier of Glasgow, who still continues to take an active part in their administration. At a comparatively recent period his attention was directed to the great need which existed for sanatoria in which phthisical patients belonging to the poorer classes might be treated, and a building, erected for this purpose at some distance from the Orphan Homes, was opened rather less than two years ago. It contains 30 beds, is for females only, and is full, while more than 40 suitable cases are waiting for admission. The quantity of butcher's meat consumed by each patient is about 3 lb. (weight before cooking) daily, to which there have to be added fish, ham, milk, butter, eggs, bread, fruit, &c , the cost per head being about £2 weekly, so that about £3000 per annum are required for maintenance alone. A second sanatorium will be ready for occupation next summer It will accommodate 40 patients and it also is to be for females. With an average residence of four months it will be possible to treat about 240 patients in the two buildings in a year. Admission is free and none but necessitous patients are eligible. An earnest appeal is therefore made for funds for carrying on the work. The medical advisory board consists of Sir William Gairdner, Professor J. G. McKendrick, Dr. D Yellowlees of the Glasgow Royal Lunatic Asylum, and Dr. Ebenezer Duncan. The first annual report of the medical officer (Dr Thompson Campbell) showed that on Nov. 1st, 1898, there were 25 patients in residence, and that during the year 56 were admitted, giving a total of 81 treated; of these 56 were discharged after an average residence of 156 days, and 25 remained on Oct. 31st, 1899. Of the 56 discharged 12

(i.e., 21 per cent.) were cured; the tubercle bacillus had disappeared and further testing by inoculation had negative results. A description of the daily routine of life in the institution is given in the general report. The secretary is Mr. D. Hill Jack, Hebron, Bridge of Weir, Renfrewshire.

THE ENGLISH-SPEAKING PRACTITIONER IN ITALY.

OUR Rome correspondent writes under date March 13th: The Cabinet Council lately held to formulate the conditions under which foreign medical men may practise in Italy has approved the following "progetto di legge" (Bill) which the Premier, General Pelloux, who is also Minister of the Interior, has presented to the Chamber of Deputies: "For the last clause of Article 23 of the law on Public Health of Dec. 22nd, 1888, No. 5849, the following has been substituted. 'From the present prohibition are excepted, first, the foreign physicians and surgeons expressly called in for special cases or for exclusive attendance on a specified individual or family, and, secondly, those who, possessing a diploma of some university or medical school abroad, practise their profession among foreign visitors only, always, however, on the understanding that the said visitors belong to States which accord the same privilege to Italian physicians and surgeons.'" The Bill, so conceived and worded, is preceded by His Excellency's vindication of its distinctive provision—a vindication which amounts to this, that as, for instance in the British Islands, Italians are not allowed to practise even among their compatriots exclusively without possessing a British qualification the permission hitherto enjoyed by British practitioners to practise among their fellow countrymen exclusively in Italy must be withdrawn. Only under conditions of perfect reciprocity can the British practitioner attend patients in the Italian Kingdom. Such is the significance and *animus* of the Bill shortly to be discussed in the Italian Chamber. THE LANCET's view of the "reciprocity" argument is well known in Italy, and it will be interesting to see the consideration that will be accorded to it by the supporters and the opponents of the Bill respectively.

OPERATION FOR TUMOURS OF THE SPINAL CORD.

SCHULTZE[1] reports two successful cases of tumour of the spinal cord diagnosed and treated surgically, thus adding to the list of 20 similar cases published by Bruns in which beneficial results had been obtained only in six. The first patient, a woman, aged 49 years, suffered from hysterical and neurasthenic symptoms which were succeeded by signs of spinal disease, symptoms of compression of the spinal cord, and paraplegia. The localising symptoms pointed to the mid-dorsal region and on operation a tumour was discovered compressing the cord in the region of the fourth to the seventh dorsal segments and lying between the dura mater and the vertebræ. This was removed and for a week after the operation the symptoms grew worse, after which they steadily improved and in a few months the patient was able to walk and to get about freely. The second case was that of a man, aged 28 years, with symptoms of spastic paraplegia and with an area of anæsthesia extending up to the level of the mid-dorsal segment of the cord. On opening the spinal canal a tumour was found at the level of the sixth dorsal vertebra and was removed. The sensory and motor troubles temporarily grew worse during the few days succeeding the operation. After this the patient improved steadily and was able to walk about and to follow his occupation as a gardener. Schultze points out that these two cases throw a more favourable light on the statistics of operation for spinal tumours, and that in view of the utter hopelessness and futility of expectant and palliative treatment there is every reason why surgical operation should be resorted to when once the diagnosis of intra spinal tumour is confirmed.

THE INTERNATIONAL CONGRESS OF PROFESSIONAL MEDICINE AND MEDICAL DEONTOLOGY.

THE Committee of the International Congress of Professional Medicine and Medical Deontology, which will be held in Paris from July 23rd to July 28th, 1900, have sent us the following information concerning the Congress to which we desire to call the attention of our readers. All persons subscribing to the Congress before June 20th, 1900, will be able to obtain a reduction of 50 per cent. in the fares over the various railway systems of France and a reduction of 30 per cent. on board the steamers of the Compagnie Transatlantique. The necessary vouchers to obtain these reductions will be sent out at the same time as the card of membership of the Congress and the railway ticket will be available for a term of one month—namely, from July 20th to August 20th. With reference to the question of apartments in Paris the committee is at present in communication with various agencies to obtain special terms. Various circulars and information upon this subject are at the present time in the hands of the President and Secretaries of the French Committee of Patronage and the different national foreign committees, and members of the Congress desirous of information upon this subject are requested to apply to such committees. Membership of the Congress may be obtained by sending 15 francs for full members (*titulaires*) and 10 francs for other members (*participants*) with a visiting card to the treasurer of the Congress, M. Pierre Masson, 120, Boulevard St. Germain, Paris. "Other members" include medical students and the wives of members of the Congress. They can obtain the reduction in railway fares but are not entitled to the publications of the Congress.

A MEETING of the general committee and subscribers to the Hampstead Heath Extension Scheme will be held at the Vestry Hall, Haverstock-hill, N.W., on Wednesday, March 21st, at 5 30 P.M., for the purpose of receiving the report of the Executive Committee and considering the recommendation as to the disposal of the funds still in hand

Lieutenant-Colonel Arthur Thomas Sloggett, R.A.M.C., and Mr. Edmund Owen, F.R C.S. Eng., have been appointed Knights of Grace of the Order of the Hospital of St John of Jerusalem in England.

NEWTON ABBOT JOINT HOSPITAL.—At the meeting of the committee held on March 9th, Mr. Ley, F.R.C.S. Eng., the medical superintendent, reported that during 1899 there had been 13 cases of typhoid fever treated, all of which had recovered.

CARDIFF INFIRMARY.—The financial position of the infirmary is occupying a considerable amount of attention in Cardiff. In spite of the appeals made last year the total income of the institution was £105 less than in 1898. Through lack of funds the committee were obliged to close the women's ward last September and unless some scheme is devised for increasing the revenue it is feared that there may be some further curtailment of the work of this excellent charity. The total deficit balance of the infirmary is now £8946, the expenditure having been in excess of the income for some years. During the years 1897, 1898, and 1899 the expenditure of the institution was £7405, £8529, and £9051 respectively, whilst the income for the same periods was £6641, £7085, and £6980. Several means have been suggested for placing the infirmary in a sound financial position and it has been recommended to municipalise the institution and allow it to be supported out of the rates.

CROOK v. CROOK AND HORROCKS

(BY A LEGAL CORRESPONDENT.)

THE recent divorce case in which the petitioner and co-respondent were medical men calls for more than passing comment. Stated briefly, the facts were that a wife suddenly told her husband that she had committed adultery. Her husband believed her and instituted proceedings, making the person she named co-respondent, with the result that as her confession was evidence against herself alone and as she did not substantiate it, but, on the contrary, denied the truth of it in the witness box, there was no evidence against the co-respondent, while the jury, after he had been dismissed from the case, were asked to consider whether the wife had or had not committed adultery. This illogical and absurd situation, arising through the strict application of the rules of evidence, is not a new one and was forced upon the public notice in 1886, when a prominent politician was found by a jury, under the judge's direction, not to have committed adultery, while the married woman on whose confession the petition was grounded was found to have committed adultery with him. The only possible way of preventing the return of verdicts which, though doubtless correct in theory, in fact suggest conditions beyond the grasp of human intelligence, would be to forbid the reception of such confessions in evidence without the way being first paved for them by the giving of such evidence as would materially *corroborate* them. In the proof of crime the evidence of one witness is sufficient at common law; but on the trial of certain charges, among which are some of those which women and young girls are prone to make, the prisoner by statute may not be convicted unless there be corroboration of the woman or girl's statement in some material particular, while no judge would allow a man to be convicted of any serious offence against a woman's chastity without the production of some evidence beside her own indicating his guilt, or at least pointing to the crime having been committed, while, again, the lunatic who from time to time gives himself up to the police as having committed murder is not so much as put upon his trial unless there are facts discovered which bear out his story, the first one necessary to be ascertained being that a death, which may have been murder, has taken place. Those who know the proneness of women in certain conditions of health to accuse themselves of unchastity and others of violating their persons will have read the trial of the divorce petition in which Dr. Peter Horrocks, obstetric physician at Guy's Hospital, was made co-respondent with little short of horror.

Amplifying the facts which we have given above as far as we have space to do so we find that they were as follows. Dr. H. E. Crook, a medical practitioner at Margate, who had been for some years married, finding that his wife was suffering from some uterine trouble sent her to consult Dr. Horrocks, with whom he was acquainted through having been a student under him at Guy's Hospital. Mrs. Crook visited Dr. Horrocks at his house in 1896, was attended by him subsequently at a private hospital, and went to see him with regard to her health on other occasions, the last of these being in 1898, shortly after she had been delivered of a child. It was given in evidence, apparently as bearing upon the suggestion of improper intimacy, that on one occasion Dr. Horrocks gave his patient a lift in his brougham to the railway station and bought her a book and a newspaper, that on another occasion he showed her over his house, and that on her asking him to be godfather to her baby he assented and wrote the child a letter, while on yet another day he sent the mother a Christmas card. If in these circumstances without anything further happening Mrs. Crook had accused Dr. Horrocks of improper familiarity with her it might have been said that either her statement was true or that her hallucination had little or nothing to account for it, not that it is always necessary to account for hallucinations. In 1899, however, a very singular event occurred. Dr. Crook went to consult, not an eminent physician or surgeon, but a person practising the cryptic science of palmistry. This lady, for the palmist was of the fair sex, seems to have made a deep impression upon Dr. Crook in some measure owing to her having told him that he ought to have been a barrister and not a medical man, in which she may or may not have been right, and also owing to her being mysteriously able to reveal to him matters connected with his past life. Dr. Crook does not seem to have told his wife all that the palmist said to him, but he imparted enough with regard to her, including her name and address, to send Mrs. Crook also in search of revelations. Put briefly, what the palmist said to Mrs. Crook was that she (Mrs. Crook) had committed adultery and would be divorced, occasioning great scandal thereby, and having first told her victim that she had a son, which was not the case, altered this to the prediction of the birth of a boy the father of whom was not to be her husband. It was some months after this astonishing interview that Mrs. Crook startled her husband by telling him that she had committed adultery "heaps of times" with Dr. Horrocks in his consulting room, subsequently amplifying her statement and reducing it to writing.

Nothing beyond this verbal and written statement was produced in evidence at the trial bearing directly on the question at issue, as before the case came on for hearing Mrs. Crook had been to see Dr. G. H. Savage. Dr. Savage was called and gave evidence that he found her feeble with a rather rapid pulse and a determined aspect almost amounting to sullenness. He appears to have suggested to her that her confession was the result of hallucination, which suggestion she accepted and maintained on oath at the hearing of the petition for divorce. Looking at the case from every point of view, and with the most anxious desire to treat the evidence on both sides with scrupulous fairness, it is impossible to believe that there is anything to be added to what Dr. Savage said. Those who read the evidence, which was fully reported in many newspapers, may have formed the view that the husband was sincere in his belief in his wife's guilt but a little unduly vehement in the expression of his opinion—a little too disinclined to admit the possibility that, with regard to his wife's temperament and condition, he might be in error. And all will admit that if charges of this kind can be made in the way recorded above and substantiated with no better evidence the position of the medical man, and particularly that of him who devotes himself to gynæcology, becomes one of grave difficulty and danger. The very examinations that he is daily compelled to make are suggestive of the offence which he may be accused of committing, while his patients are frequently those most predisposed to accept such suggestion. In the case of Dr. Horrocks the lady who accused him not only did not do so till after she had visited the palmist but apparently did not afterwards allege that she ever felt any conscientious scruples before that occasion, nor did the palmist apparently suggest them. As far as the evidence goes, it is entirely consistent with the view that the palmist simply told her victim that she had in fact committed adultery and would at some future time be divorced and the impression of guilt having been produced the feelings of bitter remorse followed naturally and developed rapidly.

How can a repetition of such terrible stories be prevented? Readers of THE LANCET are well aware that to treat all patients consistently as strangers is not always practicable, any more than it is to have a third party always present when a woman enters the consulting room. This last precaution, moreover, would be no unvarying protection, for it is almost as easy for a woman to say that adultery took place on some imaginary occasion as to assign it on a real one. To prove a negative where such charges are made is frequently impossible and particularly so where the date fixed is one long past. Wherefore, all that is possible for the medical man is to do his duty steadily and courageously, trusting that his fair fame may never be assailed but that if it ever should be the friends whose esteem he has earned will stand by him in his need. In an old number of *Punch* we light upon an apt summary of his destiny which includes:—

> "To face and brave the gossip and stuff
> That travels about through a country town,
> To be thrown in the way of hysterical girls
> And live all terrible scandals down."

Scandals take a good deal of "living down" and it is to be regretted that the law permits them to be made public except in cases where their truth is capable of being proved to the satisfaction of reasonable men.

THE WAR IN SOUTH AFRICA.

HISTORY is fast making itself in South Africa, where events are following one another with dramatic rapidity. The capital of the Orange Free State is now in the hands of Lord Roberts's advancing army. The existence of the South African Republics on their old basis is surely, if slowly, coming to an end, notwithstanding that they threaten to continue fighting for their independence and the maintenance of their existing political autonomy; but they must have been perfectly aware when they launched their ultimatum and promptly followed it up by the invasion of Her Majesty's dominions that the political independence of the Republics was at stake. Lord Salisbury's telegraphic despatch of March 11th in reply to one from the Presidents of the South African Republics puts the case as it is viewed in this country and leaves no possible room for doubt. The war is not over, but things are nevertheless nearing an end. The British military machine at the beginning of the campaign was neither sufficiently strong for the purpose nor was it in proper working order. It is both now, and under the direction and guidance of very able military leaders. What is wanted is the requisite time and patience for the continuance of its further operations and for the unfolding and evolution of the military schemes on the fulfilment of which Lord Roberts and his subordinate generals are now occupied.

It is gradually being borne in upon the public mind that when the history of this war comes to be written it will be found that the futile attempts of the Boers to take Mafeking, Kimberley, and Ladysmith have, after all, served our purpose far more effectually than critics in this country have believed. Sir George White's contention was probably quite correct. The occupation of Ladysmith frustrated the strategical schemes of the Boers, saved Natal from being ravaged, and Pietermaritzburg, and possibly Durban, from being invested, notwithstanding that it caused the division of our forces and delayed the execution of our own plans for the conduct of the campaign.

It is remarkable how little we have known about the losses in the Boer forces from wounds and sickness. Their returns of these have been quite unreliable and ridiculously low, probably with the object of concealing their losses in the field from relatives and friends in the Transvaal and the Free State. We may assume that the ratio of the wounded to the killed has been about five to one in their case, but we have no means of knowing the actual number of their killed in battle, for they always try to carry off as many of their dead as possible.

The total list of our own casualties from the commencement of the war up to a recent date is estimated at 15,849, of whom 2041 have been killed and 9356 wounded, while 930 have died from disease. The relatively small number of the latter says much for the care and forethought that have been taken in providing for the requirements of the campaign and for the sanitation of the camps that have been occupied by the troops. It is possible that the amount of disease will increase as the campaign goes on, but if we are to have no more troops shut up in besieged garrisons, which is happily likely to be the case now, one of the main causes for the prevalence of serious sickness will have been removed. Taking the losses as a whole they are, when compared with some of our former wars, less than might have been expected, especially considering the number and severity of the fights that have occurred. A considerable number of the wounded have recovered sufficiently to return to their regiments. The Mauser rifle is a merciful weapon on the whole. Shell-wounds are, however, as might be expected, as grave and fatal as ever they were. The surgical experience acquired during the campaign is likely to add to, and in some respects to revolutionise, our knowledge and ideas about gunshot injuries. Sir William MacCormac and Mr. Treves are on their way home, and their admirable notes on the surgery and diseases of the war, the condition of the hospitals, and the medical arrangements generally, will be much missed. Among the diseases contracted in the field the sufferers from dysentery are, perhaps, most to be pitied. The catarrhal form of this disease is happily the variety most prevalent in South Africa, for it is the mildest and most easily curable; but where the disease severe, attended with ulceration, and becomes chronic, is, as everyone knows, a very distressing malady, liable frequent recurrence from slight causes, and often attend with complications and followed by long-continued perio of ill-health and debility. The chief public anxiety at t

FIELD FORCE.—SERVICE ABROAD.

Medical Division, War Office, Feb. 20th, 1900.

present moment is in regard to the relief of Mafeking, which is said to be hard pressed and to be suffering considerably from diseases brought about by the hardships and conditions of the siege. This little garrison has held out so long and pluckily under its gallant, vivacious, and resourceful commander that it has throughout attracted keen interest and all are anxiously waiting for its speedy relief.

(NOTES FROM SIR WILLIAM MAC CORMAC.)

(*Continued from p. 614.*)

On Feb. 5th I visited the hospital at Estcourt under the command of Major W. Dowman, R.A.M.C. This is a most comfortable little hospital occupying the chapel, school, and convent school, a few beds also being placed in marquees and bell tents. The authorities of the Roman Catholic convent have very kindly placed their premises at the disposal of the Royal Army Medical Corps and the sisters most effectually carry on the nursing duties of the hospital. They are the Mother Superior and seven nuns of the order of St. Augustine, superintended by Father Follis, and they are most attentive and efficient in their nursing duties. This hospital was organised on Nov. 4th. It consists of 100 beds, which can be increased to 130. A gentleman of Durban has presented 50 spring bedsteads of a very comfortable variety, the remainder of the beds being of the ordinary spring hospital pattern. A very suitable operating room has been equipped in a room off the chapel. The remainder of this building also contains beds. The convent schoolhouse next door is occupied by 14 beds on the ground floor and 14 upstairs. Across a small valley at the other side of the town is situated the town schoolhouse in which 40 beds are placed, whilst two marquees near at hand take eight beds each. There are suitable bathrooms on the premises and the Royal Engineers have erected a cookhouse and good latrines in convenient situations. This hospital did most excellent work during the earlier period of the campaign before the medical organisation had assumed such vast proportions as at present. It was the place of refuge for the wounded after the battle of Willow Grange which was fought only a few miles away between Estcourt and Mooi river. The wounded were attended to on that occasion by Major Dowman and his small staff, assisted by one civilian surgeon, and on their convalescence or fitness for removal were transferred to Pietermaritzburg. I consider the work done at this hospital to be very satisfactory. Amongst the cases treated was that of a sergeant of the Border Regiment who was shot in the abdomen by a sentry for failing to respond to his challenge. Dr. Neal, a civilian surgeon, operated upon him. He found it necessary to remove 15 inches of small intestine which had been perforated in several places by the bullet. This man fortunately made a perfect recovery.

Frere, Feb. 10th, 1900.

I and my secretary arrived here yesterday afternoon and took up our quarters with Major F. A. B. Daly, R.A.M.C. This officer is in charge of No. 1 Stationary Field Hospital, No. 4, which was originally here (on my last visit in December), having gone 26 miles away to Spearman's Farm on the left flank of our position. Major Daly was captured by the Boers after the battle of Dundee and was a prisoner in their hands for nearly three months. He relates many interesting details concerning the Boer medical arrangements and did much during his captivity towards alleviating the sufferings of the enemy's wounded in addition to his duties with our own wounded prisoners. He eventually excited so much jealous feeling on the part of the Boer doctors that it was decided to send him back and so he was despatched to Durban, *viâ* Delagoa Bay, last month. The Boer wounded thanked him in generous terms for his kindness to them through the medium of the *Diggers' News.* This hospital at present is almost entirely used as a resting place and dressing station for the wounded on their long journey from Spearman's Camp to Mooi river, Pietermaritzburg, and Durban. The hospital was started on Jan. 11th on the ground close to the railway line vacated by No. 4 Stationary Field Hospital (*vide* my letter in THE LANCET of Jan. 13th). The sick and wounded arrive here by hand stretchers and ambulance waggons from Spearman's Camp (24 miles away) and the ambulance trains are loaded at the siding emptying the hospital as rapidly as possible. Unfortunately, the number of wounded has been lately so great that the trains cannot get them away fast enough to prevent accumulation. The fighting having now ceased for a season the accumulation will be cleared off and affairs will soon right themselves. The hospital on its arrival here on Jan. 11th consisted of only one-half of an ordinary field hospital—viz., 50 beds—but shortly after the second half arrived, and it then consisted of a well-equipped and comfortable resting place of 100 beds. This latter accommodation was soon found to be quite inadequate for the large convoys of wounded constantly arriving from Spearman's Camp. No. 4 Stationary Hospital there consisted of 400 beds, and the hospital here was consequently increased to 260 beds. This was accomplished by adding 16 marquees and 15 more bell tents. At present, therefore, the hospital consists of 16 marquees (each containing six or eight beds) and 40 bell tents (equipped with rubber sheets and blankets only for the less serious cases). Two marquees are reserved for officers. The marquees in which serious cases are accommodated are equipped with spring bedsteads, sheets, quilts, and blankets, also mosquito curtains, fans, tarpaulins on the floor, and, in fact, everything which can be thought of to lessen the sufferings of the wounded who must of necessity remain for a time in this hot, dusty, and fly-stricken place. A night-stool is placed outside each marquee for serious cases and the trivially wounded are provided with latrine pits outside the hospital lines. Enteric stools are carried away by Indian natives who disinfect the contents with perchloride of mercury and then bury them. The drinking water is obtained from the little stream near at hand known as Frere river. It is pumped up by a pumping engine and put into precipitating tanks. At its best it is very muddy and unpleasant. The hospital is well supplied with ice, which can be kept for eight days after its arrival by employing a simple device used by Major Daly. A deep hole has been dug in the ground, in which a false bottom of wood has been placed, this latter having been pierced with holes. The ice is placed in this hole and the melted portion runs through the holes in the flooring into the space beneath. This method is found very serviceable, and soda-water bottles can be placed on top. The strength of officials consists, in addition to Major Daly, of two civilian surgeons (one of whom is ill), one quartermaster of the Royal Army Medical Corps, and one assistant surgeon of the Indian Subordinate Medical Establishment. I consider that this hospital is very carefully managed and is suitably and comfortably equipped for the purposes for which it is used.

On my arrival I was informed that our whole army, with the exception of General Warren's brigade, was on its way in from Spearman's Camp to Frere and Chieveley and that in consequence the hospital at Spearman's Camp had been entirely vacated by the sick and wounded, the convoy bringing them along being expected to arrive before dark. It appears that on the decision having been arrived at that the army must retire the question was put to the seriously wounded officers and men as to whether they would rather remain behind and fall into the Boer hands or suffer the pain and risk necessarily incurred by being carried over a rough road across country a distance of 24 miles. These wounded—although many were very severely and many dangerously wounded—all stated their wish to remain with their own people and to be conveyed on, and so the hospital was struck and the patients were despatched at once by stretchers and wagons. Each stretcher was carried by Indian coolies, four being at work at a time and 12 coolies being attached to each stretcher. This method of transport has been in use ever since Spearman's Camp was started, but up to the present the serious cases could always remain in hospital until it became safe to move them. The wagons have been also in use for trivial cases not requiring hand carriage. This system of employing coolies is a continuation of the idea of using civilian accessory bearers at the battle of Colenso and subsequent battles across the Tugela (mentioned in my letter descriptive of the Colenso battle of Dec. 15th, 1899). The hand carriage greatly minimises the misery of the wounded and the present scheme in use is very good.

The long, dusty, rough road, if it deserves that name at all, is a track running from Frere to Spearman's Camp made by the tremendous traffic of baggage wagons and ammunition carts which have passed over the undulating, grassy country to the west of Frere during the last month. It is very rough and uneven. As we sat last evening gazing at the rapidly setting sun we overlooked a long stretch of road reaching as far as the eye could distinguish. About seven o'clock, just on the approaching sudden darkness of the tropics, a barely distinguishable moving mass of men could be seen coming over a distant hillock. This was the leading stretcher of the convoy and it had reached us before the end of the train of stretchers and wagons came into view. Hot bovril and stimulants had already been prepared by the men of the Royal Army Medical Corps, great pots of the former resting in the kitchen.

The hospital is surrounded by barbed wire fencing to prevent confusion and the entrance of unauthorised persons. There is an opening at one side at which Major Daly immediately stationed himself, accompanied by his staff sergeant. Each stretcher was lowered at this entrance, the nature of the wound was inquired into, and the patient after identification was conveyed by the men of the Royal Army Medical Corps to the vacant beds, a list of which was kept by the staff sergeant (each tent being numbered). Confusion was thereby greatly diminished and none of the native stretcher bearers were allowed to enter the enclosure; 43 stretchers and 12 wagon loads (100 cases) completed this convoy and most of the cases were serious. I was informed that there were still another 150 to arrive on the morrow. This terribly long line of brave fellows lying helpless, arriving one by one in the dusky light, coming over the horizon, accompanied by the moving shadows of the bearers, silently advancing in their bare feet, or singing a peculiar chant of their own as they wearily sped beneath the weight upon their shoulders, presented one of the most impressive and saddest sights imaginable, and every few moments the sad scene was lighted up by bright lightning flashes, making it still more pitiable. For 14 hours, with the exception of a short halt at midday, had this weary body of sufferers, sick with their wounds and sad at heart with their defeat, wended its way across the hot and dusty veldt. The day happened to be a terribly hot one. The lanterns of the hospital attendants flitted hither and thither among the tents. Wounds had to be rebandaged, splints readjusted, morphia injected, and in some cases operations to be performed at once. The orderlies moved about as rapidly as possible from tent to tent, the similarity of the tents in the darkness causing confusion in anyone unfamiliar with the exact location of the different patients. I was immediately consulted concerning the advisability of re-amputation in a case of secondary hæmorrhage following amputation in the upper third of the leg; the poor fellow was, however, too ill for operative interference and died about two hours after his arrival. Such a sight as No. 1 Stationary Field Hospital presented on the night of my arrival brings home in a most vivid and distressing manner the awful realities of war. One's feelings are very different from those experienced by merely reading about or hearing of such things. This scene was only one of many similar ones at this hospital; the convoys of wounded have been arriving at short intervals ever since Jan. 1st. I am informed that No. 4 Stationary Field Hospital, which consisted of 400 beds at Spearman's Camp two days ago, bivouacked last night in the open veldt on their way to Chieveley. The brigade field hospitals are still at Springfield (beyond Spearman's) with Warren's Brigade and contain 100 wounded between them; all of these will come in to-morrow.

Chieveley, Feb. 10th

We arrived here early this morning from Frere. Since the battle of Colenso there has been very little change here in the arrangement of things. The naval guns are booming today from the position of the old battlefield. These guns continually shell the Boer positions overlooking Colenso town, and beneath their fire and also that of the Boer shells lies the body of poor Captain Hughes, R.A.M.C., in the grave constructed by his brother officers after the Colenso battle. The station-master's house here (the only house) has been surrounded by iron plates taken from the armoured train and also by a network of ropes, these latter being for the purpose of stopping fragments of shells Small earthworks have also been erected in the near vicinity of the house and barbed wire laid down in suitable places as a stumbling-block for the enemy. A little collection of the graves of those who died in the hospital here after the Colenso battle tells its own tale. These graves have been neatly arranged by the soldiers themselves and alongside those of the men lie the remains of two officers, one of whom was the only son of

Lord Roberts. A tombstone has been erected upon which is recorded the fact that Lieutenant Roberts was killed whilst performing an act of conspicuous gallantry which earned for him the Victoria Cross. At present the medical arrangements here consist of one bearer company and a field hospital under the command of Major C. W. Thiele, R.A.M.C. The hospital contains very few patients, and these few are mostly of a medical nature. No. 4 Stationary Field Hospital is arriving here to day, as are also most of General Buller's force. Sir Redvers Buller himself is expected to take up his quarters this evening in the station-master's house.

The army having retired with no apparent hope of relieving Ladysmith in the near future, and I having received a telegram from Lord Roberts to the effect that he would like me to be with him at the front at Modder river, I purpose starting immediately for Durban *en route* for Port Elizabeth and Modder river.

WILLIAM MAC CORMAC.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

(Continued from p. 643.)

THE parts of Lord Llandaff's report which have not been summarised in the previous articles have reference to (1) the purchase of provincial water undertakings by local authorities; (2) the consideration of the present and prospective requirements of London with regard to the quantity and quality of the water-supply; (3) a statement of the reasons which lead the Commissioners to advise that a new Water Board should be constituted to purchase the present undertakings and to be responsible for the supply of the whole of Water London; and (4) suggestions as to the composition of the proposed Water Board and as to the powers with which it should be invested.

The Commissioners hoped to be able to get some valuable assistance from a consideration of the cases of purchase of provincial water undertakings by local authorities, but they found that no certain conclusions could be drawn from the accounts received from county boroughs. To arrive at definite conclusions it would have been necessary to examine each case separately and to know the capital, the income, and the rates of charges of the company which was bought by the corporation, and to obtain full information as to the income, and the charges after purchase by the cor- n. It would have been necessary also to know defi- he area supplied and the changes which had occurred rateable value of the area. From the information hey received the Commissioners think, however, that ppears to be no superior economy in corporation ment or that the charges for water are as a whole d by it. Corporations, however, have the advan- being able to distribute the burden of the charges water-supply between the consumers and the rate- , and also of charging at higher rates in districts the area of their boroughs. In one case the Com- ers were able to obtain particulars with regard to se by arbitration.

he year 1878 the Stockton and Middlesbrough Corporations bought the water company which supplied those places. The share capital amounted to £250,388 and the company were paying their maximum dividends. The purchase of the undertakings was authorised by the Stockton and Middlesbrough Act of 1876 By this Act, it was directed that £18,647 (their maximum statutory dividends) should be paid in perpetual annuities, or that a gross sum calculated on 25 years' purchase of that amount should be paid together with any further sum which an arbitrator might direct to be given for compulsory sale and for the prospective value of the undertaking. The debts of the company, £126,073, were taken over by the corporations. The capital value of the annuities was £466 175, and £213,803 were awarded by the arbitrator for "compulsory sale and prospective value." Thus altogether the corporation paid £679,977 for a business of which the share capital was £250,388. After the purchase of the undertaking the water trust expended £997,341 in obtaining a new supply of water. The result was that in 1897 there was a deficit on the water income amounting to £26,629 This was met out of the borough rates of the purchasing boroughs and the rate amounted to 11 6*d* in the pound.

Of all the cases examined that of the purchase by the Glasgow Corporation was the most favourable from the point of view of the water consumers. In the year 1855 the corporation bought two companies' undertakings paying perpetual annuities at the rate of 5·13 per cent. on the capital of the companies which were at the time paying 6 per cent. The corporation obtained Parliamentary sanction for the supply of water to outlying boroughs and were allowed to fix themselves the rates which were to be paid provided that they did not exceed those previously charged by the companies. In 1859 a new supply of water was obtained by gravitation from Loch Katrine. For a few years there was a deficit and for two years increased rates and then the corporation were able to reduce the water rates from 1*s*. 2*d*. to 1*s*. and later to 6*d*. in the pound rental. The Commissioners were not able to obtain information as to the growth of the rateable value in the district supplied and that they consider a material circumstance in estimating the financial results of the purchase.

The Commissioners proceed to consider what the legitimate requirements of the inhabitants of Water London now are, what the requirements are likely to be in the future, and what bearing those requirements have on the expediency of purchase. The requirements are, they report, a supply of pure and wholesome water constantly laid on at such pressure as will make the water reach the top storeys of the highest houses and in quantity an amount sufficient to meet for some time the growing needs of the inhabitants. London is mainly supplied from the rivers Thames and Lee, which are liable to pollution, and therefore in order to ensure the purity of the water vigilance and careful treatment are necessary. *The Duke of Richmond's Commission* in 1869 and Lord Balfour's Commission in 1893 recommended improved conservancy and efficient filtration. Increased powers have been given to the Thames Conservators and much improvement has been effected by them. The Metropolis Water Act of 1852 places the companies under the obligation of "effectually filtering all river water before it is distributed." Efficient filtration was formerly judged by the clearness and limpidity of the filtered water effluent and if this was found to be clear when viewed through a tube 2ft. in length it was supposed to be efficiently filtered. A new test of efficient filtration has more recently been introduced by Dr. Koch of Berlin, who by means of cultivating bacteria and counting their number in samples of water found that their number was decreased by filtration. He considered that efficient filtration is secured if the effluent does not show more than 100 microbes per cubic centimetre after a period of incubation lasting for 48 hours. The late Sir Edward Frankland adopted Koch's standard of efficient filtration, but he stated in his evidence that it was a purely arbitrary one, sufficient though not unduly severe when applied to the filtered river water, from which are derived the chief supplies of the London water companies, yet he desired it to be understood that the infraction of this standard does not throw suspicion on the wholesomeness of the water. The Commissioners point out that in the tables they have examined, which show the number of microbes in the water supplied by the companies, the microbial excess is in some very large, and unless it should be found that Sir Edward Frankland's standard is too high it seems to follow that the companies' works and processes require to be enlarged and improved. They think, however, that neither the cause of bacterial excess in samples of filtered water nor the methods of filtration best adopted to reduce that excess can be laid down and defined with any certainty. It would, they observe, doubtless be possible to throw on the companies the task of carrying out more systematic and frequent examination of the samples of water and to make the works necessary to obtain a bacterial standard of purity which would be practically safe and satisfactory. They, however, are "disposed to adopt the view" that the work of scientifically treating river derived water should be entrusted to the hands of a public authority, and that it would be an advantage to obtain a unity of management and a uniformity of arrangement which are now absent.

A constant supply of water, the Commissioners point out, is not at present given to all the houses in Water London. About 72,000 are intermittently supplied. The obligation under which the water companies are placed with regard to height above the ground at which they must supply water varies in the different companies. Of late public institutions and other buildings have been raised above the statutory limits of supply, and if the upper storeys receive water it must at present be given as "a matter of grace and not of right. A change in the vertical limits of supply could not be effected without legislation nor could the additional obligations be imposed on the companies without their consent or without compensation." If some public authority purchased the undertakings water would doubtless be supplied under constant pressure to the highest houses.

With regard to the adequacy of the present available sources of water the Commissioners report that in their opinion unification of the water undertakings by purchase would tend to secure a sufficiency by a more rational and economical system of distribution and would lead to a further increase of the intercommunication between the present separate supplies. The existing arrangements have partitioned Water London "in a fortuitous manner" and the arrangements for pumping, service reservoirs, and distributing pipes have been arranged on arbitrary lines of demarcation which are accepted by the companies and which are perpetual barriers to the passage of water from one district to another in spite of the fact that physical circumstances call for a different arrangement. As an example of this the Commissioners refer to the evidence of the engineer to the East London Company who thought that if the undertakings were in the hands of one authority the supply derived by the New River from the Lee would be used for the East London district and that the western parts of the New River district would be supplied by water derived from the Thames. All problems which present themselves in connexion with extension and enlargement of the water supply would be simplified if conventional barriers against the free passage of water from one district to another were swept away, and this would happen if the water undertakings were acquired and managed by a single public authority. The prevention of waste of water would also be more easily controlled by a public authority than by the present water companies. Parliament and the public have been opposed to giving to trade companies a power of entry into dwellings, of regulating fittings, and of cutting off water supplies; but these powers are exercised without "cavil" by public authorities. At the present time the companies do not obtain "the sympathy and assistance" of the public, because efforts for the prevention of waste result in profit to the shareholders of the companies. But the assistance of the water consumers would be of great value to the supplying authority because under a system of constant supply the consumption of water is practically in the hands of the consumers, and the Commissioners believe that a properly constituted authority would receive general assistance from the public in preventing wilful waste.

With respect to the amount of water which will be necessary in the future the Commissioners think it sufficient to look forward to the year 1941, and they adopt Lord Balfour's estimate which they think errs, if at all, on the safe side. The Balfour Commission estimated the amount of water required per head at 35 gallons a day, and applying these figures to the estimated population of Water London the daily supply required for 12,000,000 of people would be 423,000,000 gallons a day. The Balfour Commission estimated the available supplies as follows: from the Lee, 52,500,000 gallons; from wells in the Lee valley, 40,000,000 gallons; from wells in the Kent Company's district, 27,500,000 gallons; and from the Thames, 300,000,000 gallons, making a total of 420,000,000 gallons. The cost of obtaining this supply and the possibility of obtaining the estimated amount from the Thames depend, the Commissioners say, on various conditions, some of which have been presented in a new light by the experience of three years of drought—the years 1893, 1898, and 1899.

UNIVERSITY COLLEGE, CARDIFF.—At the meeting of the council of University College, Cardiff, held on March 2nd (under the presidency of Dr. W. T. Edwards), Dr. E. Walford, medical officer of health of the county borough of Cardiff, and Dr. William Williams, medical officer of health of Glamorganshire, were appointed lecturers on Public Health and Hygiene in connexion with the department of public health recently established in the college. A vote of thanks was awarded to Mr. H. Hughes for presenting to the medical school the medical library of the late Mr. John Hughes, F.R.C.S. Eng., of Carmarthen.

THE MIDWIVES BILL.

THE DIVISION ON THE SECOND READING.

ON Mr. Heywood Johnstone bringing forward a motion for the Second Reading of this Bill on Friday, March 9th, Mr. T. P. O'Connor unsuccessfully moved the adjournment of the debate. The original question was then put that the Bill be read a second time, when the Ayes were 124, and the Noes 34. The following are the names of the Members who voted:—

AYES.

Name.	Constituency.	Politics.
Arrol, Sir William	Ayrshire, South ...	Liberal Unionist.
Ashton, Thomas Gair ...	Bedfordshire, Luton ...	Liberal.
Baker, Sir John	Portsmouth	Liberal.
Bayley, Thomas	Derbyshire, Chesterfield	Liberal.
Beach, Right Hon. Sir M. H.	Bristol, W.	Conservative.
Begg, Ferdinand Faithfull	Glasgow, St. Rollox ...	Conservative.
Bolton, Thomas Dolling	Derbyshire, N.E.	Liberal.
Buchanan, Thomas Ryburn	Aberdeenshire, E. ...	Liberal.
Burns, John	Battersea and Clapham	Liberal.
Burt, Thomas	Morpeth	Liberal.
Cameron, Robert ...	Durham, Houghton-le-Spring	Liberal.
Campbell-Bannerman, Sir H.	Stirling	Liberal.
Cavendish, V. C. W. ...	Derbyshire, W.	Liberal Unionist
Cawley, Frederick ..	Lancashire, Prestwich	Liberal.
Channing, Francis Allston	Northamptonshire, E ...	Liberal.
Charrington, Spencer ..	Tower Hamlets, Mile End	Conservative.
Colomb, Sir John Charles Ready	Great Yarmouth	Conservative.
Colville, John	Lanarkshire, N.E. ...	Liberal.
Cooke, C. W. Radcliffe ...	Hereford	Conservative.
Corbett, A Cameron ...	Glasgow, Tradeston ...	Liberal Unionist
Cornwallis, Fiennes Stanley W.	Maidstone	Conservative.
Courtney, Right Hon. Leonard H.	Cornwall, Bodmin ...	Liberal Unionist.
Crombie, John William ..	Kincardineshire	Liberal.
Curran, Thomas B.	Donegal, N.	Nationalist.
Dalkeith, Earl of	Roxburghshire	Conservative.
Davies, M. Vaughan ...	Cardiganshire	Liberal.
Dixon-Hartland, Sir Frederick Dixon ...	Middlesex, Uxbridge ...	Conservative.
Dunn, Sir William	Paisley	Liberal.
Emmott, Alfred...	Oldham	Liberal.
Evans, Samuel T.	Glamorganshire, Mid....	Liberal.
Fenwick, Charles	Northumberland, Wansbeck	Liberal.
Fergusson, Right Hon Sir J.	Manchester, N E.	Conservative.
Field, Admiral	Sussex, Eastbourne ...	Conservative
Finlay, Sir Robert Bannatyne	Inverness Burghs... ...	Liberal Unionist
Fisher, William Hayes ...	Fulham	Conservative
Flannery, Sir Fortescue ..	Yorkshire Shipley... ...	Liberal Unionist.
Foster, Harry S.	Suffolk, N.	Conservative.
Gedge, Sydney ...	Walsall	Conservative
Gibbs, Hon. Vicary	Hertfordshire, Mid. ...	Conservative.
Gilliat, John Saunders	Lancashire, Widnes ...	Conservative.
Gorst, Right Hon. Sir John Eldon	Cambridge University	Conservative.
Greene, Henry D. ..	Shrewsbury	Conservative.
Gurdon, Sir William Brampton	Norfolk, N.	Liberal.
Haldane, Richard Burdon	Haddingtonshire	Liberal.
Hardy, Laurence	Kent, S.	Conservative
Hazell, Walter	Leicester	Liberal.
Henderson, Alexander	Staffordshire, W ...	Liberal Unionist
Hobhouse, Henry	Somerset, E ..	Liberal Unionist
Houldsworth, Sir William Henry ...	Manchester, N W. ...	Conservative
Hubbard, Hon, Evelyn .	Lambeth, Brixton ..	Conservative.
Hutton, Alfred E	Yorkshire, Morley ..	Liberal,
Jacoby, James Alfred ..	Derbyshire, Mid.	Liberal.
Johnston, William ..	Belfast, South	Conservative
Joicey, Sir James ...	Durham, Chester-le-Street	Liberal.
Jones, William	Carnarvonshire, N. ...	Liberal.
Kenyon-Slaney, Colonel William	Shropshire, N. ...	Conservative
Kimber, Henry .	Wandsworth	Conservative
Lawrence, Sir E Durning	Cornwall, Truro	Liberal Unionist.

Lawson, Sir Wilfrid... ...	Cumberland, Cockermouth...	Liberal.
Leese, Sir Joseph F. ...	Lancashire, Accrington	Liberal.
Leng, Sir John	Dundee	Liberal.
Llewelyn, Sir J. T. Dillwyn	Swansea, Town	Conservative.
Loder, Gerald Walter Erskine	Brighton	Conservative
Lonsdale, John Brownlee	Mid Armagh	Conservative.
Lopes, Henry Yarde Buller	Grantham	Conservative.
Lowe, Francis William ...	Birmingham, Edgbaston	Conservative.
Lowles, John	Shoreditch, Haggerston	Conservative.
Loyd, Archie Kirkman ...	Berkshire, Abingdon ..	Conservative.
Lyttelton, Hon. Alfred ...	Warwick and Leamington	Liberal Unionist.
Macdona, John Cumming	Southwark, Rotherhithe	Conservative.
M'Kenna, Reginald... ..	Monmouthshire, N. ...	Liberal.
M'Killop, James	Stirlingshire	Conservative.
Maddison, Fred.	Sheffield, Brightside ...	Liberal.
Martin, Richard Biddulph	Worcestershire, Mid. ...	Liberal Unionist.
Melville, Beresford Valentine	Stockport	Conservative.
Milward, Colonel Victor .	Warwickshire, Stratford-on-Avon	Conservative.
Molloy, Bernard Charles	King's County, Birr ...	Liberal.
Monckton, Edward Philip	Northamptonshire, N. .	Conservative
Monk, Charles James ..	Gloucester	Liberal Unionist.
Moore, Arthur	Londonderry City	Nationalist.
Moore, William	Antrim, N.	Conservative.
More, Robert Jasper ...	Shropshire, Ludlow ..	Liberal Unionist.
Morrell, George Herbert .	Oxfordshire, Woodstock	Conservative.
Murray, Charles J.	Coventry	Conservative.
Norton, Captain Cecil William	Newington, W.	Liberal.
O'Connor, Arthur	Donegal, E.	Nationalist.
Oldroyd, Mark	Dewsbury	Liberal.
Orr-Ewing, Charles Lindsay	Ayr Burghs	Conservative.
Phillpotts, Captain Arthur	Devon, Torquay	Conservative.
Pickersgill, Edward Hare	Bethnal-green, S.W. ...	Liberal.
Powell, Sir Francis Sharp	Wigan	Conservative.
Pryce-Jones, Lieutenant-Colonel Edward	Montgomery District ...	Conservative.
Quilter, Sir Cuthbert ...	Suffolk, Sudbury	Liberal Unionist.
Reid, Sir Robert Threshie	Dumfries District	Liberal.
Renshaw, Charles Bine ...	Renfrewshire, W.	Liberal.
Roberts, John H.	Denbighshire, W.	Liberal.
Russell, T. W.	Tyrone, S	Liberal Unionist.
Rutherford, John	Lancashire, Darwen ...	Conservative.
Ryder, John Herbert Dudley	Gravesend	Conservative.
Schwann, Charles E. ...	Manchester, N.	Liberal.
Scott, Charles Prestwich	Lancashire, Leigh ...	Liberal.
Shaw, Thomas	Hawick District	Liberal.
Sinclair, Captain John ...	Forfarshire	Liberal.
Smith, James Parker ...	Lanarkshire, Partick ...	Liberal Unionist.
Smith, Hon. W. F. D. ...	Strand	Conservative.
Souttar, Robinson	Dumfriesshire	Liberal.
Steadman, William Charles	Tower Hamlets, Stepney	Liberal.
Sullivan, Donal	Westmeath, S	Nationalist.
Talbot, Right Hon. J. G.	Oxford University ...	Conservative.
Thornton, Percy M. ..	Battersea and Clapham, Clapham	Conservative.
Trevelyan, Charles Philips	Yorkshire, Elland	Liberal.
Ure, Alexander	Linlithgowshire, West Lothian	Liberal.
Wallace, Robert	Perth	Liberal.
Walton, John Lawson ...	Leeds, S.	Liberal.
Warner, Thomas Courtenay T.	Staffordshire, Lichfield	Liberal.
Wason, Eugene	Clackmannan and Kinross	Liberal.
Wedderburn, Sir William	Banffshire	Liberal
Whiteley, George	Stockport	Liberal.
Williams, John Carvel ...	Nottinghamshire, Mansfield	Liberal.
Wilson, John	Durham, Mid	Liberal.
Wilson, John	Falkirk	Liberal Unionist.
Wilson, John	Lanarkshire, Govan ...	Liberal.
Wilson, J. W.	Worcestershire, N. ...	Liberal Unionist.
Wortley, Right Hon. C. B. Stuart-	Sheffield, Hallam	Conservative.

Tellers for the Ayes, Mr. Heywood Johnstone and Mr. Tennant.

NOES.

Name.	Constituency.	Politics.
Abraham, William	Cork, N.E.	Nationalist.
Allsopp, Hon. George ...	Worcester	Conservative.
Austin, M.	Limerick, W.	Nationalist.
Blundell, Colonel Henry .	Lancashire, Ince	Conservative.
Caldwell, James	Lanarkshire Mid.	Liberal.

Wilson-Todd, Wm. H. ...	Yorks, Howdenshire ...	Conservative.
Wyvill, Marmaduke D'Arcy	Yorks, Otley	Conservative.

Tellers for the Noes, Mr. T. P. O'Connor and Mr. Robert Ambrose.

THE STANDING COMMITTEE ON LAW.

On Feb. 23rd the chairman of the Committee of Selection (Mr. Halsey) reported to the House that they had nominated the following Members to serve on the Standing Committee for the consideration of all Bills relating to law and courts of justice and legal procedure which may by order of the House be committed to such Standing Committee:—Mr. Asquith, Mr. Atherley-Jones, Mr. Atkinson, Mr. Barlow, Mr. Bartley, Mr. Beach, Mr. Butcher, Mr. Carew, Mr. Coghill, Dr. Commins, Mr. Radcliffe Cooke, Viscount Cranborne, Mr. Cripps, Mr. T. B. Curren, Mr. Bromley-Davenport, Sir Charles Dilke, Mr. Dillon, Mr. Tatton Egerton, Mr. Arthur Elliot, Mr. Samuel Evans, Sir George Fardell, Sir Robert Finlay, Mr. Flynn, Mr. Lewis Fry, Mr. Sydney Gedge, Sir Frederick Godson, Mr. Goulding, Mr. Graham, Mr. H. D. Greene, Mr. Haldane, Mr. Harwood, Mr. T. M. Healy, Mr. Helder, Mr. Hemphill, Mr. Staveley Hill, Mr. Hobhouse, Sir John Jenkins, Mr. Johnson-Ferguson, Mr. Lees Knowles, Mr. W. F. Lawrence, Sir Joseph Leese, Mr. Loder, Mr. A. K. Loyd, Mr. MacNeill, Sir Henry Meysey-Thompson, Colonel Milward, Mr. Monk, Mr. Lloyd Morgan, Mr. Mount, Mr. Graham Murray, Captain Norton, Mr. Pickersgill, Sir Francis Powell, Colonel Pryce-Jones, Sir Robert Reid, Mr. Rentoul, Sir Matthew White Ridley, Mr. Bryn Roberts, Sir Andrew Scoble, Mr. Parker Smith, Mr. Ernest Spencer, Mr. Stevenson, Mr. Ure, Sir Howard Vincent, Mr. Robert Wallace (Perth), Mr. Warr, Sir James Woodhouse, and Mr. Woods.

The following Members of Parliament have been specially added to the Standing Committee on Law in respect of the Midwives' Bill:—Mr. Ambrose, Mr. Cosmo Bonsor, Mr. Flower, Mr. Gibbs, Mr. Hazell, Mr. J. Howard, Mr. Humphreys Owen, Mr. Heywood Johnstone, Sir P. Milbank, Mr. T. P. O'Connor, Sir George Pilkington, Mr. Schwann, Mr. Tennant, Mr. Thornton, and Mr. Tritton.

COCKLES AND TYPHOID FEVER.—Dr. W. H. Webb, the medical officer of health of Kingsbridge, Devon, states that the death-rate for 1899 was 12 8 per 1000 and the birth-rate 19 2 per 1000. The only case of typhoid fever was clearly due to eating raw cockles from the estuary of the river where the sewage of the town has its outfall.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on March 8th, the Senior Vice-President, Mr. H. G. HOWSE, being in the chair.

Mr. W. H. A. JACOBSON was introduced, and having made a declaration in the terms of the oath prescribed by the Charter of 1800, was admitted a member of the Court of Examiners.

The Chairman of the Board of Examiners in Dental Surgery reported that at a meeting on Feb. 21st the Board, with the object of carrying out the decision arrived at by the Council on Feb. 8th, adopted the following resolution, viz.:—

> That time spent in the capacity of assistant to a dental surgeon in one of the hospitals attached to the army in South Africa, not exceeding a period of six months, be allowed to count in lieu of the completion of any courses of dental or general professional study which such students were undergoing during this present winter session, and in lieu of any dental or general courses which such students would ordinarily be required to attend during the ensuing summer session, on the understanding that allowance will only be made for the number of months, not exceeding six, during which such students shall be in the service of the hospital, and for which a satisfactory certificate from the dental surgeon can be produced.

Proposals for alterations of several by-laws were submitted to the Council; these alterations are chiefly connected with admitting to the Fellowship examinations, under certain conditions, candidates with qualifications especially recognised by the Council without requiring them to pass the examinations of the Conjoint Examining Board. The proposals were approved and were referred to a committee.

A report from the Committee on the Midwives Bill was read and adopted; it contained *inter alia* the following clause:—

> No provision has been made that the licensed midwife should "apply for qualified medical assistance in every case attended by a midwife which presents symptoms of difficulty, abnormality, danger, or disease on the part of the mother or the new-born child." The addition of a clause to this effect was recommended by the General Medical Council and supported by the Council of this College. The committee understand from their chairman, the representative of the College on the General Medical Council, that the Executive Committee of that Council have again represented to the Privy Council the necessity of such a provision, and they are of opinion that this further action of the General Medical Council should receive the support of the Council of this College.

It was resolved to send a copy of the report of the Committee to the General Medical Council and to the honorary secretary of the Midwives Bill Committee.

A committee was appointed to consider the award of the Walker prize. This is a prize which was founded by Mr. Charles Clement Walker with the object of encouraging the investigation of the pathology and therapeutics of cancer. Although it is not intended that essays should be submitted in competition for the prize or that those who are anxious to obtain it should be called upon to submit their names as candidates, yet it is hoped that the knowledge of the reward which may be obtained and the distinction which it will confer on its recipient will prove an incentive to those who are occupied in the study of this disease. The prize is open to persons of all nationalities, and the Council will be glad for information from time to time of investigations that are being pursued in relation to this disease, so that they may be furnished with all that is necessary to guide them in selecting the fittest recipient for the prize. The prize is awarded every five years and amounts to £100.

The next meeting of the Council will be held on April 5th.

THE MEDICAL DEFENCE UNION.

THE annual general meeting of the Medical Defence Union was held at St. Martin's Town Hall on March 13th, Dr. W. S. A. GRIFFITH, the President, being in the chair.

The CHAIRMAN moved the adoption of the report which is dealt with in a leading article and referred to the honorarium of 100 guineas which had been voted to the treasurer. Thanks were due to the members of the council for the great sacrifices which they made in time whilst travelling to and from the council meetings. He mentioned the solicitor to the Union, Mr. Hempson, as having the entire confidence of the council and acknowledged the services of the general secretary, Dr. A. G. Bateman.—The motion was seconded by Dr. BRIDGWATER and was ultimately carried after a discussion on the subject of the proposed amalgamation with the London and Counties Medical Protection Society.—The CHAIRMAN said it was a difficult matter and any discussion might cause misunderstandings to arise.—Mr. M. HOUGHTON said he understood that the London and Counties Medical Protection Society offered to accept the Union's terms, but this was loudly denied by the members present and the CHAIRMAN said that the council had decided not to amalgamate.

On Dr. J. A. MASTERS proposing that the accounts be received, adopted, and entered upon the minutes a long discussion took place as to how and when annual subscriptions were to be paid, when and how long a member was "out of benefit" of the society, and when membership ceased.—Mr. HOUGHTON'S idea was that on the notice convening the meeting there should be a reminder to those who had not paid their subscription.—A Member supported this view, and the CHAIRMAN having accepted it, Dr. ELLISTON seconded the adoption of the accounts, which was passed, but not before Dr. ROSE had initiated another long debate concerning the *amount of money received* by the Union for costs allowed in successful actions.—Mr. HEMPSON explained the position, how when members of the Union were attacked by people earning a few shillings a week, upon the costs for the defence being awarded, it was useless and waste of money to proceed against men of straw.

The sum of £100 was voted for payment of travelling expenses of members attending the council meetings.

Dr. DANFORD THOMAS proposed and Dr. F. A. PURCELL seconded for election as members of council: Mr. T. G. Alderton, Dr. W. Rigden, and Dr. Arthur Jones.—Speaking on the principle of how members should be chosen for election Dr. COLLIE went in some detail into the particular methods adopted and he was supported by Dr. ROSE in objection to the council nominating members for election, the latter gentleman also remarking that an introduction of fresh blood on the council was desirable.—Dr. LOVELL DRAGE interposed to say that the council merely put forward the names of suitable candidates and it was perfectly open to other gentlemen to nominate their own "cocks" to fight on the other side. It ended in Dr. Rose and Dr. Collie contesting with the three gentlemen already named for the places on the council, but Dr. Alderton, Dr. Rigden, and Dr. Jones were declared elected.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 7297 births and 4553 deaths were registered during the week ending March 10th. The annual rate of mortality in these towns, which had been 25·8, 24·2, and 21·2 per 1000 in the three preceding weeks, further declined last week to 20·4. In London the rate was 18·8 per 1000, while it averaged 21·5 in the 32 provincial towns. The lowest death-rates in these towns were 14·3 in Brighton and in Swansea, 14·9 in West Ham, 15·1 in Birkenhead, and 15·5 in Croydon; the highest rates were 28·9 in Preston, 29·1 in Liverpool, 31·4 in Wolverhampton, and 32·4 in Salford. The 4553 deaths in these towns included 424 which were referred to the principal zymotic diseases, against 469, 445, and 424 in the three preceding weeks; of these 131 resulted from whooping-cough, 120 from measles, 85 from diphtheria, 33 from scarlet fever, 32 from "fever" (principally enteric), and 23 from diarrhœa. No death from any of these diseases occurred in Brighton, Birkenhead, or Gateshead; in the other towns they caused the lowest death-rates in Swansea, Huddersfield, and Halifax, and the highest rates in Wolverhampton, Leicester, Salford, and Preston. The greatest mortality from measles occurred in Plymouth, Cardiff, Wolverhampton, Leicester, Salford, and Preston; and from whooping-cough in Wolverhampton, Liverpool, Bolton, Salford, Oldham, and Preston. The mortality both from scarlet fever and from "fever" showed no marked excess in any of the 33 towns. The 85 deaths from diphtheria included

41 in London, eight in Leicester, six in Leeds, five in Sheffield, and five in West Ham No fatal case of small pox was registered last week in any of the 33 large towns There were seven cases of small pox under treatment in the Metropolitan Asylums Hospitals on Saturday last, March 10th, against eight, 11, and seven in the three preceding weeks, one new case was admitted during the week, against none, three and two in the three preceding weeks The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1777, against numbers decreasing from 3578 to 1868 on the 16 preceding Saturdays, 147 new cases were admitted during the week, against 159 160, and 154 in the three preceding weeks Influenza was certified as the primary cause of 37 deaths in London The deaths referred to diseases of the respiratory organs in London, which had been 527, 485 and 380 in the three preceding weeks, further declined to 378 last week, and were 193 below the corrected average The causes of 70, or 1 5 per cent, of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Croydon Bristol, Oldham, Leeds, and in seven other smaller towns, the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Liverpool, and Sheffield

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 31 7 and 29 0 per 1000 in the two preceding weeks, further declined to 27 7 during the week ending March 10th but exceeded by 7 3 per 1000 the mean rate during the same period in the 33 large English towns The rates in the eight Scotch towns ranged from 13 2 in Leith and 22 4 in Edinburgh to 31 9 in Paisley and 32 0 in Perth The 857 deaths in these towns included 25 which were referred to diarrhœa, 24 to whooping cough, 17 to measles, 10 to scarlet fever, nine to "fever," and seven to diphtheria In all 92 deaths resulted from these principal zymotic diseases, against 69 and 74 in the two preceding weeks These 92 deaths were equal to an annual rate of 3 0 per 1000 which was 1 1 above the mean rate last week from the same diseases in the 33 large English towns The fatal cases of diarrhœa which had declined from 20 to 18 in the three preceding weeks, rose again last week to 25 of which 14 occurred in Glasgow, three in Edinburgh three in Dundee and three in Greenock The deaths from whooping cough which had been 18, 17, and 15 in the three preceding weeks rose again to 24 last week, and included 11 in Glasgow, four in Aberdeen three in Edinburgh, and three in Paisley The fatal cases of measles which had been 17 and 20 in the two preceding weeks declined again last week to 17, of which 12 were registered in Glasgow and three in Paisley The deaths referred to scarlet fever, which had been 11, nine, and 10 in the three preceding weeks, were again 10 last week, and included five in Glasgow, three in Edinburgh, and two in Greenock The fatal cases of "fever," which had increased from two to six in the three preceding weeks, further rose last week to nine of which five occurred in Glasgow and three in Edinburgh The deaths from diphtheria which had been five in each of the two preceding weeks rose to seven last week, and included five in Glasgow The deaths referred to diseases of the respiratory organs in these towns, which had been 382 and 324 in the two preceding weeks further declined to 259 last week, but exceeded by 87 the number in the corresponding period of last year The causes of 28, or more than 3 per cent, of the deaths in these eight towns last week were not certified

HEALTH OF DUBLIN

The death rate in Dublin, which had been 51 0 and 34 3 per 1000 in the two preceding weeks rose again to 36 8 during the week ending March 10th During the past four weeks the death rate in the city has averaged 41 1 per 1000 the rate during the same period being 20 6 in London and 24 3 in Edinburgh The 247 deaths registered in Dublin during the week under notice were 17 in excess of the number in the preceding week, and included 10 which were referred to the principal zymotic diseases against 11 and 12 in the two preceding weeks, of these three resulted from diarrhœa two from measles, two from diphtheria two from "fever," and one from scarlet fever These 10 deaths were equal to an annual rate of 1 5 per 1000, the zymotic death rate during the same period being 1 6 in London and 2 2 in Edinburgh The deaths referred to diarrhœa which had been two four, and five in the three preceding weeks, declined again to three last week The fatal cases of measles, which had been five and one in the two preceding weeks, rose to two last week The deaths referred to different forms of "fever" which had been three, one, and four in the three preceding weeks declined again last week to two The mortality from diphtheria slightly exceeded that in the preceding week The 247 deaths in Dublin last week included 40 of infants under one year of age and 64 of persons aged upwards of 60 years, the deaths of infants slightly exceeded the number in the preceding week while those of elderly persons showed a decline Six inquest cases and two deaths from violence were registered, and 84, or more than a third, of the deaths occurred in public institutions The causes of 13 or more than 5 per cent, of the deaths in the city last week were not certified

VITAL STATISTICS OF LONDON DURING FEBRUARY, 1900

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality during February in each of the 43 sanitary areas of London With regard to the notified cases of infectious diseases in the metropolis, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 7 0 per 1000 of the population, estimated at 4 589 129 persons in the middle of this year In the three preceding months the rates had been 12 6 8 8 and 8 0 respectively The rates were considerably below the average in Chelsea St James Westminster, St Giles, St Martin in the Fields, Strand and St Olave Southwark sanitary areas, while they showed the largest excess in Limehouse St Saviour Southwark, Rotherhithe Greenwich Woolwich and Lee Four cases of small pox were notified during February, of which two belonged to Woolwich one to Fulham, and one to Poplar sanitary areas, six small pox patients were admitted into the Metropolitan Asylums Hospitals during the month and seven remained under treatment on Saturday, March 3rd The prevalence of scarlet fever showed a further decline from that recorded in recent months among the various sanitary areas this disease showed the highest proportional prevalence in Stoke Newington St Olave Southwark, Wandsworth, Lewisham Lee, and Plumstead The Metropolitan Asylums Hospitals contained 1827 scarlet fever patients at the end of February, against 3343, 2797, and 2126 at the end of the three preceding months, the weekly admissions averaged 152 against 304, 197, and 180 in the three preceding months The prevalence of diphtheria showed a continued decrease from that recorded in recent months, this disease was proportionally most prevalent in Fulham Limehouse, St Saviour Southwark, Bermondsey, Camberwell and Lee sanitary areas There were 1402 diphtheria patients in the Metropolitan Asylums Hospitals at the end of February, against 1718, 1679, and 1572 at the end of the three preceding months, the weekly admissions averaged 165, against 227 184, and 189 in the three preceding months The prevalence of enteric fever in London showed a further considerable decline from that in recent months, among the various sanitary areas this disease showed the highest proportional prevalence in St Luke, St George in the East Mile End Old Town, Poplar, Rotherhithe and Battersea The Metropolitan Asylums Hospitals contained 274 enteric fever patients at the end of February against 460 406, and 289 at the end of the three preceding months, the weekly admissions averaged 40 against 76, 52 and 40 in the three preceding months Erysipelas was proportionally most prevalent in Bethnal Green Limehouse, Newington Rotherhithe, and Plumstead sanitary areas The 23 cases of puerperal fever included four in Lambeth and two each in Paddington, Chelsea St Pancras Shoreditch, Newington, Camberwell and Greenwich sanitary areas

The mortality statistics in the table relate to the deaths of persons actually belonging to the various sanitary areas of the metropolis, the deaths occurring in the public institutions of London having been distributed among the sanitary areas in which the patients had previously resided During the four weeks ending March 3rd the deaths of 7185 persons belonging to London were registered, equal to an

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING FEBRUARY, 1900.

* Including 17 cases of membranous croup.

† Including deaths from membranous croup.

annual rate of 20·4 per 1000, against 17·6, 27·3, and 27·3 in the three preceding months. The lowest death-rates last month in the various sanitary areas were 11·6 in Hampstead, 13·1 in Stoke Newington, 15·0 in Wandsworth, 15·4 in Lee, 17·2 in St. George Hanover-square, and 17·4 in Lewisham; the highest rates were 27·3 in St. Saviour Southwark, 27·7 in St. George Southwark, 29·1 in City of London, 31·4 in St. Luke, 32·6 in Holborn, and 35·8 in St. Olave Southwark. During the four weeks of February 626 deaths were referred to the principal zymotic diseases in London; of these, one resulted from small-pox, 166 from measles, 25 from scarlet fever, 157 from diphtheria, 171 from whooping-cough, 71 from enteric fever, 35 from diarrhœa, and not one either from typhus or from any ill-defined form of continued fever. These 626 deaths were equal to an annual rate of 1·8 per 1000, against 1·9, 2·1, and 1·9 in the three preceding months. No death from any of these diseases was recorded last month either in St. Martin-in-the-Fields or in Strand sanitary areas; in the other sanitary areas they caused the lowest death rates in Paddington, Stoke Newington, St. Giles, and City of London, and the highest rates in Fulham, Clerkenwell, St. Luke, Poplar, St. Olave Southwark, and Bermondsey. The fatal case of small-pox belonged to Woolwich sanitary area. The 166 deaths referred to measles were slightly below the average number in the corresponding periods of the ten preceding years; this disease was proportionally most fatal in Hammersmith, Fulham, St. James Westminster, Shoreditch, Newington, and St. Olave Southwark sanitary areas. The 25 fatal cases of scarlet fever showed a decline of 35 from the corrected average; the greatest proportional fatality from this disease occurred in Hampstead, Hackney, Clerkenwell, Whitechapel, Woolwich, and Plumstead sanitary areas. The 157 deaths from diphtheria showed a slight decline from the average number in the corresponding periods of the ten preceding years; among the various sanitary areas this disease was proportionally most fatal in Poplar, St. Saviour Southwark, St. George Southwark, Bermondsey, Rotherhithe, and Lee. The 171 fatal cases of whooping-cough were 89 below the corrected average number; this disease showed the highest proportional fatality in Clerkenwell, St. Luke, Bethnal Green, Mile End Old Town, Bermondsey, and Woolwich sanitary areas. The 71 deaths referred to enteric fever were nearly double the average number in the corresponding periods of the ten preceding years; among the various sanitary areas the highest proportional mortality from "fever" occurred in Fulham, Holborn, Mile End Old Town, St. George-in-the-East, Poplar, and St. Saviour Southwark. The 35 fatal cases of diarrhœa were considerably below the corrected average; this disease was proportionally most fatal in Fulham, Clerkenwell, Holborn, St Saviour Southwark, and Lewisham sanitary areas. In conclusion, it may be stated that the aggregate mortality from these principal zymotic diseases in London during February was nearly 17 per cent. below the average.

Infant mortality in London last month, measured by the proportion of deaths of children under one year of age to registered births, was equal to 133 per 1000. The lowest rates of infant mortality were recorded in St. George Hanover-square, Stoke Newington, St. Giles, St. Martin-in-the-Fields, Strand, and Lee; and the highest rates in Westminster, Holborn, City of London, Limehouse, Bermondsey, and Rotherhithe sanitary areas.

THE SERVICES.

"BLACKWOOD" AND THE ROYAL ARMY MEDICAL CORPS.

Blackwood's Magazine for the present month has a long and interesting article on the Royal Army Medical Corps and the grand work which it has done on the battlefields and in the army hospitals of South Africa. In December, 1895, "Maga," it will be remembered, took up the cudgels on behalf of the Army Medical Department and summed up its history, more especially with reference to the anomalous condition in which it had been left by the country's Government, despite the fact that it had always proved itself to be an admirable and deserving service. In the article of that date, the writer now tells us with justifiable satisfaction, the subject was treated "in a manner, which she *is* proud to believe, gained the gratitude of the department and had some influence in moving the authorities to make necessary reforms." The contribution to the present number of *Blackwood* is written in a highly appreciative and eulogistic spirit in connexion with the admirable work done by the Royal Army Medical Corps in the present war, and it adds to the sum of the medical officers' indebtedness to the writer for her advocacy of their claims to the grateful consideration of the army and the nation. The present Secretary for War, as we all know, most wisely granted the medical officers what they rightly desired and for what we many years ago contended—namely, that they should be formed into a special corps bearing the distinction of "Royal." This was done and due military rank was also conferred upon its officers. They were consequently put upon their mettle and went out to the present war with the full determination to do their best under the new order of things, to fulfil all that was expected of them, and it is indisputable that they have been amply justified by the results obtained in South Africa. The writer in *Blackwood* assures us that the medical service of the army there has attracted the cordial admiration of continental—and particularly Russian—military surgeons by its performance of duty in the field and the completeness of its arrangements. Of the medical arrangements as a whole and of the nature and variety of the work done by the officers of the Royal Army Medical Corps in South Africa there is now no need to tell. It is admitted on all sides to have been admirable. For probably the first time in war the medical service has had power in proportion to its responsibility and it has exercised its powers aright. It is only due to Lord Lansdowne to say that never before have the medical and hospital requirements been provided on so liberal a scale or been better adapted and applied for the comfort and benefit of the sick and wounded. Nor has attention to practical army hygiene in the field been neglected, for great care seems to have been exercised in this direction. The medical service has well indicated its claims to public confidence.

ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Fleet Surgeon W. H. Patterson to the *Victorious*. Staff Surgeons: J. C. Ferguson to the *Wallaroo*, lent to the *Europa*; G. Hewlett to the *Charybdis*, undated; and W. E. Home to the *Boscawen* for the *Minotaur*. Surgeons: L. Kilroy to the *Hibernia*: L. E. Dartnell to the *Ganges*; C. J. E. Cock to the *Victorious*, D. W. Hewitt to the *Goliath*; J. Stoddart and H. B. Hall to the *Vernon*; R. St. G. S. Bond, lent to Yarmouth Hospital; and A. G. Eastment to the *Cossack*.

THE IMPERIAL YEOMANRY.

To be Medical Officers, with the temporary rank of Captain: A. E. Vidler, Lieutenant, 1st Cinque Ports Volunteer Rifle Corps, and E. T. Shorland.

ROYAL ARMY MEDICAL CORPS.

The undermentioned officers are granted the temporary rank of Captain while serving in South Africa:—Surgeon Captain Charles Edward Douglas, 6th Volunteer Battalion the Black Watch (Royal Highlanders); Surgeon-Captain George G. Oakley, 1st Volunteer Battalion the Duke of Wellington's (West Riding Regiment). The undermentioned officers are granted the temporary rank of Lieutenant whilst serving in South Africa:—Surgeon-Lieutenant Robert W. Michell, 4th Volunteer Battalion the Suffolk Regiment; Surgeon-Lieutenant James C. Taylor, 9th Lanarkshire Volunteer Rifle Corps. Surgeon-Captain C. Stonham, Middlesex Yeomanry Cavalry, Officer in command and Chief Surgeon, Imperial Yeomanry Field Hospital, is granted the temporary rank of Major whilst serving in South Africa. The undermentioned Surgeon-Captains are granted the temporary rank of Captain whilst employed in South Africa:—Andrew A. Watson, 2nd Volunteer Battalion the East Lancashire Regiment; C. A. MacMunn, 3rd Volunteer Battalion the South Staffordshire Regiment; J. K. Butter, 2nd Volunteer Battalion the South Staffordshire Regiment. The undermentioned Surgeon-Lieutenants are granted the temporary rank of Lieutenant whilst serving in South Africa:—George Black, 2nd Volunteer Battalion the Royal Sussex Regiment; James R. Atkinson, 2nd Cheshire Royal Engineers (Volunteers); Albert E. Morison, 1st Volunteer Battalion the Durham Light Infantry.

ARMY MEDICAL RESERVE OF OFFICERS.

The undermentioned Surgeon Captains to be Surgeon-Majors: J. W. Cook and James Mill.

any of its powers of supervising the conduct, &c., of midwives to a district council. This should be opposed. There are 139 county and borough councils in England and Wales, and 1491 urban and rural district councils. What is the good of appointing 1491 "supervising authorities?" Besides, the members, especially of rural district councils are not those who should be entrusted with the chief administrative *duties in the Bill. The county councils should themselves* act.

6. No penalty is provided if a midwife attend other than "natural labours," or if she give a certificate of stillbirth.

7. The Bill neglects to provide that "any person" may prosecute; Clause 14 puts it upon a district council, this being placed upon the district councils, and this authority will always refuse to prosecute.

8. The Bill excludes Scotland and Ireland, although midwives registered in England can act as midwives in Scotland and Ireland, and no provision is made to supervise them there.

9. No provision is made for the punishment of practitioners or midwives—other than those appointed by the Bill—if they examine or grant documents to intending midwives.

10. Clause 17 provides that the English Branch Council "shall" act for and in the name of the General Medical Council. This is a very dangerous precedent.

11. A clause should be inserted making it penal on both parties if a practitioner employ a midwife as his midwifery assistant.

12. In Clause 18 the term "midwife" should mean a midwifery nurse who undertakes to act only as a nurse to women in childbirth.

If those practitioners who know that their M P.'s will support a good Bill, and one which will place midwives under close police supervision (as a good number of M.P.'s support a Bill for the latter purpose only) will send the above proposed amendments to them, perhaps good will follow. Practitioners must not think that because the Bill has been read a second time it is certain to pass. Every Government since 1890 has refused to adopt the Bill. So if only each practitioner and his friends will oppose the Bill it is not likely to pass.

I am, Sirs, yours faithfully,

Liverpool, March 10th, 1900. R. R. RENTOUL.

HERNIA OF THE URINARY BLADDER.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 3rd Mr. Moynihan, in his third Arris and Gale Lecture, gives an exhaustive account of the above condition. I am surprised to find no reference, in those cases where a cyst has been opened and found to contain fluid resembling urine, to testing the reaction of the escaping fluid with litmus paper. In those cases where the urine has decomposed this method is, of course, useless, but in a large number of cases where the urine is fairly normal it will be found to be acid. This acidity has, so far as I know, only been found in cyst contents in the inguinal region in the case of urine. Therefore, excluding the very remote chance of a hernia of kidney or ureter or an extravasation of urine, the cyst containing the clear yellow fluid must be bladder. I have been in the habit of employing this test for some years and am so impressed by its practical utility that I always carry litmus paper in my operation bag. The time saved by this simple test will be appreciated by those surgeons who have been unfortunate enough to accidentally open the bladder when operating for hernia or performing cœliotomy, as the time taken in repairing the bladder is quite long enough without spending a further period in injecting the bladder or in passing sounds.

I am, Sirs, yours faithfully,

Plymouth, March 11th, 1900. C. HAMILTON WHITEFORD.

A NEW MINERAL SPRING AT NAUHEIM.

To the Editors of THE LANCET.

SIRS,—A boring has been in progress here for four months under the direction of Geheime Bergrat Dr. Lepsius, Professor of Geology at the Hessian Grand Ducal Polytechnic College of Darmstadt, and yesterday a new effervescing thermal brine spring rose from a depth of 207 metres. The present temperature of the water is 89° F., but will probably after complete development of the spring rise to 95°, the temperature which exists at some depth below the surface. The quantity of carbonic acid gas is to all appearance so abundant that analysis will probably show a percentage of this gas even higher than that of the two similar springs, No. 7 and No. 12, at Nauheim which have up to now been considered the most strongly effervescing thermal springs in Europe. Thanks to this new spring there will be such an abundance of mineral water for bathing purposes that for a long time to come any demand in this respect will be amply satisfied. Nauheim has thus obtained a valuable and ample increase of its curative resources. I am, Sirs, yours faithfully,

Bad Nauheim, March 8th, 1900. PROFESSOR SCHOTT, M.D.

"PULSATING EMPYEMA."

To the Editors of THE LANCET.

SIRS,—In an annotation on pulsating empyema on page 719 of THE LANCET of March 10th reference is made to *Comby's description of the disease which appeared in 1891 in* the *Archives de Médecine* as the most complete study of the disease. In justice to an Irish writer, the late Dr. Robert MacDonnell of this city, I would draw your attention to his monograph, "Contributions to the Diagnosis of Empyema, with Cases" (Hodges and Smith, Dublin, 1844). Nothing has been added to our knowledge of the disease since then and I feel sure that THE LANCET would not willingly or knowingly deprive a British physician of his laurels to wrongly bestow them on a foreigner.

I am, Sirs, yours faithfully,

Dublin, March 12th, 1900. GEORGE FOY.

"THE POSITION OF THE RETIRED ARMY MEDICAL OFFICER."

To the Editors of THE LANCET.

SIRS,—The question raised very properly by "Retired on Gratuity" in THE LANCET of March 10th will probably be satisfactorily dealt with by the Departmental Committee of the House of Commons. There is also the larger question of army medical officers, being the only officers in Her Majesty's navy or army resigning on a gratuity, being held "liable to recall to service" up to 55 years of age, after the answer of Mr. St. John Brodrick, then Under-Secretary of State for War, in answer to Colonel Welby's question—viz., "All officers (except subalterns and captains) resigning on a gratuity are liable to recall to service up to 44 years of age."

I am, Sirs, yours faithfully,
H. G. GARDNER, M.B., C.M. Edin.

Norris-street, S W., March 13th, 1900.

CERTAIN DEFICIENCIES IN OUR INFIRMARIES AND ASYLUMS.

To the Editors of THE LANCET.

SIRS,—Patients in infirmaries often say: "I like the place well enough; I do not find any fault with either the treatment or food, but I am very much annoyed with my fellow patients—that one over there snores horribly—that one over there coughs terribly—that other one over there raves continually, and that other one talks incessantly, &c." Now, in these days when people live at high pressure and neurotic diseases predominate over all others, are these annoyances fully considered by the medical attendants of infirmaries? Could anything be done to mitigate them? Would smaller wards suffice? or would portable partitions (of a material that would not conduct sound readily) between beds be of any use? The above complaints are so common and must seriously retard the recovery of many patients that they should be seriously considered by the powers that be in infirmaries Then in asylums patients suffering only from a few delusions often say: "It was cruel of you to send me here among such a crew; how can you expect me ever to get well here, with that one singing constantly there, that other one swearing eternally there, and this other one shouting incoherently, incessantly, &c?" No doubt superintendents of asylums grade their patients as well as they can; but it is quite impossible for them to do so properly as long as these institutions are district or parochial and they are required to take in and retain every kind of case occurring in their neighbourhood.

It is surprising that the Lunacy Commissioners do not recommend asylums to be national instead of parochial or district; then the patients could be received as now into the asylum in their neighbourhood and sent after a few weeks' observation to an institution where the companionship would at least not retard their recovery, and chronic cases might be drafted from one asylum to another, giving them a change of air and surroundings occasionally which might ameliorate their condition materially. Hoping you will find room in your invaluable journal for the above and that those who read it and have any power in these matters will give the matter due consideration,

I am, Sirs, yours faithfully,
Paisley, March 10th, 1900. JOHN B. HUNTER, M.D. Glasg.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Consultative Institute.

AN intimation has been given officially that this institute will be opened at an early date, consulting rooms having been taken and fitted up with every convenience and all modern requirements. It is also stated that the committee have secured the services of a highly qualified medical man who is to be the first consulting physician appointed to the institute. This gentleman's qualifications are given at length, and bills, pamphlets, and detailed information are said to be in process of supply to the manufactories, trading establishments, and mercantile offices of the city. It remains to be seen how far all these preparations will result in success, but I do not envy the position of the medical man who, in opposition to the profession among whom he is about to locate himself and in face of the strong expression of opinion by the leading medical press, occupies a post under such exceptional conditions.

Training Institution for Nurses.

The annual meeting of the supporters of this institution, held on Feb. 23rd, showed that much good work had been done during the year. 555 families had been attended. The number of nurses on the staff was 66, of whom 55 were trained nurses and 11 were probationers. The statement of accounts showed that there was an income of £5496 and an expenditure of £3318, leaving a balance to be carried forward of £2178. The chairman congratulated the committee and expressed his satisfaction at the substantial provision made for pensions and at the contribution made to the District Nursing Society. The usual votes of thanks were passed and Dr. Rickards was re-elected honorary physician, Mr Barling honorary surgeon, and Dr E. Malins honorary gynæcologist to the institution.

Needless Deaths of Children.

In connexion with an inquest held on a small baby the coroner expressed himself strongly on the subject of overlying as a cause of death in infants In this particular case the father, mother, and a girl occupied the bed into which the baby was taken. Obviously the smallest had the worst chance in such a condition. The coroner stated that in Birmingham 80 children died every year from suffocation, and 75 of these deaths were absolutely preventable. English mothers clung to the practice of having their children in bed with them and while they did so the risk to life would continue. It is a question whether any legislation can prevent this practice of overcrowding, but it is a lamentable fact which presses upon the consideration of humanitarians. Unfortunately, in large towns this evil is a common one and most difficult to prevent either by precept or by law.

March 13th

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Report of the Head Constable of Liverpool for 1899.

THE report of the head constable of Liverpool for the year 1899 contains much valuable information. It deals with the police establishment and the state of crime, and gives tabular returns. It is interesting to find that instruction in "first aid" to the sick and injured is now given systematically to all constables. Fifteen years ago there was hardly an exception to the absolute ignorance of the force as to what should be done in cases of accident or sickness in the streets. "Put him in a cart and send him to hospital" was the invariable rule, with what results to the unfortunate patients may be imagined. Now no fewer than 1650 constables have received certificates of efficiency from the St John Ambulance Association, and the few who have not received them (recruits, &c.) are now undergoing instruction. To prove the value of what has been done in this direction it is only necessary to mention that last year the Liverpool police rendered "first aid" in 803 cases, and that in 484 of these cases they were highly commended by the medical men who ultimately took charge of the cases. In connexion with this subject it may be mentioned that in 1882 wheeled ambulance litters were placed at every police-station in the city to provide proper means of transport; a year or two later the Northern Hospital and subsequently the Royal Southern Hospital provided horse ambulances fully equipped for their respective districts; and in January, 1898, the city council, on the recommendation of the Watch Committee, authorised the establishment in connexion with the police of a complete horse ambulance service for the entire city. The benefit of all these provisions to sick and injured persons has been incalculable. Instruction in swimming and life saving has also been introduced and now many constables have passed the tests of the National Life-Saving Society. Instruction in drill and gymnastics is also now systematically imparted to all recruits, with great advantage to health, strength, smartness, and efficiency. With regard to the crimes committed in Liverpool, the head constable reports that in the five years ended 1889 there were 30,889 indictable crimes committed in Liverpool. In the five years ended 1899 there were only 19,863 such crimes and this notwithstanding the largely increased population. The most satisfactory reduction of all is shown in crimes of violence For the five years ended 1889 these numbered 1615, whilst for the five years ended 1899 they numbered only 790. There is one offence in the reports the figures for which form a very large proportion of the total, and the great reduction of which seems to confirm and accentuate the evidence of improvement furnished by the record of indictable offences Drunkenness, black as the figures have been, shows an enormous reduction, being only one-fourth of what it was 25 years ago. At the same time the head constable remarks that he deals with "illegal" drunkenness. It is not a record of all drunkenness. For it is obvious that persons getting drunk at home, or persons who (even though the worse for drink in the streets) are not incapable or riotous or in charge of any horse or cart, commit no offence against the law. For the five years ending in 1874 the average annual number of cases of drunkenness was 19,193, whilst for the five years ending in 1899 the figures had decreased to 4768. Indictable offences last year numbered only 3504, as against 4314 in the previous year. Crimes of violence show a reduction of 52, being only 82 last year, as against 134 in the previous year. The head constable lays much stress on the diminution in all kinds of crime in Liverpool during the last 15 years, so much so that he has advised the Watch Committee to diminish the police force by 100 men.

Proposed Amalgamation of Two Liverpool Hospitals.

The Lord Mayor, in moving the adoption of the report of the committee of St. Paul's Eye Hospital at the annual meeting held on March 12th at the town-hall, referred to the usefulness and popularity of the hospital among the working-classes. The work had now outgrown the building and the people of Liverpool ought to assist the committee in providing a new hospital. The Lord Mayor alluded to the possibility of amalgamation with the Eye and Ear Infirmary in Myrtle-street, which through lack of funds had nearly 50 empty beds. He suggested that a combination of the two institutions might result in more work being done without additional cost. The suggestion appears to be a reasonable one and deserves the serious consideration of the managers of both charities.

The Milk-supply in Liverpool and Tuberculosis.

Dr. Hope (the medical officer of health) has submitted a report to the Health Committee bearing on the difficulties in the way of securing convictions for supplying tuberculous milk, from the fact that the Act required that the information should be laid, and the summonses heard, within a period less than that in which the analysis of the suspected milk could be completed. Dr. Hope advised the committee to seek for an alteration of the law, which in its present form, is practically futile.

March 13th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Health of Edinburgh.

DURING the month of February the death-rate in Edinburgh was 22 78 per 1000 of the estimated population. The average death-rate in the month of February during the preceding five years has been 20 19 per 1000. The number of infectious diseases reported during the month was markedly less than last year, being 174 as compared with 937 in February, 1899. The mortality from influenza and its complications in February was 71, as against 41 in January. The poorer districts of the city are still only slightly attacked, and up to the end of February the common lodging-houses were apparently entirely free from the disease.

Edinburgh Royal Medical Society.

On March 6th the annual President's dinner of the Royal Medical Society took place in the Edinburgh University Union. The guest of the evening was Mr. Victor Horsley. The company numbered between 60 and 70 and included Professor Simpson, Professor Chiene, Professor Schafer, Colonel Rooney, Colonel Warburton, and Surgeon-Captain Horne. The chair was taken by Dr. W. J. Barclay, one of the junior Presidents. Colonel Rooney responded to the toast for the army and closed by proposing the healths of "The Medical Officers who are about to proceed to South Africa on the Staff of the Scottish Hospital." Mr. G. L. Chiene, who is going out with his father, replied. The chairman gave the toast of "Our Guest, Mr. Victor Horsley." Mr. Horsley, who was received with loud applause, referring to the complimentary remarks regarding him made by the chairman, said that though it was perfectly true that only by means of experimental work had cranial surgery become possible, he thought the profession was too apt to forget the man to whom they owed all surgery. In Edinburgh Lord Lister's name ought to come first whenever any advance in surgery was discussed. The toast of "The Royal Medical Society" was given by Professor Simpson. Dr. G. Mackie, the junior President, replied. Mr. Horsley gave "The University and Medical Corporations," to which Professor Chiene and Professor Schafer replied.

Royal Society of Edinburgh.

At a meeting of the Royal Society of Edinburgh on March 5th, after a paper on the Dynamics of Cyclones by Mr. John Aitken, F.R.S., Dr. Aitchison Robertson read a paper on the Activity of Saliva in Diseased Conditions of the Body. He placed great emphasis on the large part played by the saliva in the digestion of starchy foods and advocated a more thorough examination of the saliva in diseased conditions.

Edinburgh Medico-Chirurgical Society.

At a meeting of this society on March 2nd there was a discussion on the Influence of Heredity on Disease. It was opened by Professor D. J. Hamilton of Aberdeen, and he was followed by a few members whose names were on the billet. By a strange lack of arrangement on the part of the officials, and contrary to all precedent in the society, no other members were asked to speak and the chairman called on the opener to reply. The debate was thus very imperfect and the want of tact on the part of the officials is being much commented upon. On former occasions a discussion of this kind has had two or three meetings devoted to it.

March 13th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Workhouse Association.

THE annual meeting of the Irish Workhouse Association was held in the Mansion House on March 9th, the Lord Mayor occupying the chair. Lord Monteagle, in moving the adoption of the report, referred to the fact that the Local Government Board now required that there should be trained nurses in every workhouse hospital, and expressed the opinion that the matter was too important to be left entirely to private enterprise, but that the training of nurses for workhouse hospitals should be specially facilitated or assisted by the Government in the same way that the training of teachers was assisted. Dr. J. W. Moore, President of the Royal College of Physicians of Ireland, in the course of an interesting speech, advocated the appointment of a medical inspector for workhouse hospitals and infirmaries, and stated his opinion that two or three lady guardians on each board could work a sort of revolution. Mr. R. L. Swan, President of the Royal College of Surgeons in Ireland, proposed the following motion:—

> That the special attention of the Executive Committee be called to the following branches of the association's work—(*a*) the conversion of workhouses into district hospitals as sanctioned and provided for by Section 90 of the Local Government Act of 1898, (*b*) the establishment of auxiliary asylums outside the workhouse for the accommodation of harmless lunatics and sane epileptics now retained in the workhouses without proper treatment or classification; (*c*) the care of the children, particularly by giving effect to the new regulations issued by the Local Government Board in May last.

Lord Clonbrock made some important observations in reference to the financial difficulties of the new and inexperienced county councils in carrying out the hospital reforms needed, and Mr. Denis Walshe, coroner for South Kilkenny, formerly medical officer of the Chorlton Hospital, Manchester, and of the Poplar and Stepney Sick Asylum, London, contributed a short but interesting account of the management of English poor-law infirmaries.

Death of Dr. T. P. Mason of Dublin.

Dr. Thomas Peter Mason died at his residence, 45, Harcourt-street, Dublin, on March 11th. He was born in Dublin in March, 1817, and was therefore aged 83 years. He filled the office of physician to Mercer's Hospital for many years, during which time he was more or less engaged in private practice in Dublin. It was, however, as a teacher and lecturer on anatomy at the Ledwich School of Medicine, of which he was a principal proprietor, that he was once so widely known. For more than 40 years Dr. Mason was closely identified with medical teaching in Dublin; his name and personality have there become familiar to hundreds, indeed thousands, of medical men now scattered over the world He obtained the M.B. degree of London University in 1846, and in 1852 he became a Fellow of the Royal College of Surgeons in Ireland. It is only a few weeks since that the death of his eldest son, Dr. Samuel R. Mason of Merrion square, who was also widely popular and highly regarded, was announced.

The Infectious Diseases Hospital, Belfast.

The question of the site for the new Belfast Infectious Diseases Hospital which, as reported in THE LANCET of March 10th, the city corporation have decided by a majority to locate at Purdysburn, has entered on a new phase owing to the action of the governors of the Belfast Asylum who met on March 12th. On this occasion (the usual monthly meeting) Dr. W. Graham, resident medical superintendent of the asylum, presented a report in which he submitted that, looking to the patients' good and successful treatment, it lay as a duty on the committee to oppose by every legitimate means the transfer of 65 acres of the Purdysburn estate proposed to be taken by the city council for the new Infectious Diseases Hospital. Should the city council persevere in their determination it would be better, Dr. Graham submitted, to abandon Purdysburn altogether and to seek another site with sufficient arable land attached to it for the use of the asylum. He pointed out that among the moral methods of treatment none was so valuable as the outdoor employment of male patients in agricultural labour, where their excitement found its best outlet and their morbid thoughts and feelings tended to run into healthier channels. If occupation and amusement could not be found for the patients the medical superintendent submitted that it would in many cases be necessary to fall back on the barbarous methods of treatment by secluding them within high walls and subjecting them to mechanical restraint. He suggested that if the committee were not satisfied fully on this question they should ask the Irish Government to obtain the opinion of their expert advisers, or, if the city council so wished, ask the highest authorities in England or Scotland whether it was just or fair to the patients to part with so large a portion of the arable land Nominally there were 295 statute acres, but from this must be deducted 112 acres for buildings courts, and woods, leaving 183 acres If 65 acres be now taken for an infectious diseases hospital it would leave 118 acres but it might be fairly estimated that the new asylum buildings would cover a surface area of 30 acres, leaving only 88 acres At a time when so many asylums were adding to their farms Dr Graham submitted that it seemed strange even to contemplate the curtailment of an estate so peculiarly adapted to the curative and recreative treatment of a most afflicted class Sir George O'Farrell (Inspector of Lunacy) who was present, in answer to questions stated that at Downpatrick Asylum they had 110 acres and they had just acquired nearly 100 acres more for 500 patients In a new asylum outside Dublin they had 465 acres and in three new asylums in Scotland the farms varied from 460 to 800 acres He spoke of the very fine site that Purdysburn was for an asylum (the most beautiful, he believed, in the world) He thought that when they deprived people who were bereft of their reason of their liberty they incurred very special obligations to them, and he considered that among these obligations was one not to bring any possible danger of spreading infectious disease In the case of small pox there would, owing to aerial spreading be a large element of risk In reply, Alderman J Graham (chairman of the Public Health Committee) said that the asylum authorities could get 500 acres in the neighbourhood at reasonable cost, and he stated that the corporation had brought the matter of erecting the Infectious Diseases Hospital at Purdysburn before the governors of the asylum as well as the Board of Control and no objection had then been made Dr Graham said it was only quite recently that the matter had come before him officially as the new medical superintendent and so he took the earliest opportunity of placing his views before his committee The report of the medical superintendent was entered on the minutes After a discussion it was decided to send a deputation consisting of the members of the Asylum Board (who were not members of the corporation) to attend the next monthly meeting of the city council to protest against taking any of the ground of the asylum at Purdysburn for an infectious diseases hospital

PARIS

(FROM OUR OWN CORRESPONDENT)

Influenza and its Treatment

AT a recent meeting of the Academy of Medicine M Huchard read a paper upon the present epidemic of influenza especially upon those abortive forms which are so common at present The attacks are characterised by an absence of fever but are accompanied by various neuralgias and depression both bodily and mental In other cases abortive pneumonias occur there is no fever but there is congestion of the bases of the lungs or else a bastard pleurisy with diminished respiratory sounds M Huchard considered that all these symptoms could be put down to some affection of the pneumogastric nerve The respiratory form is not signalised by any very definite symptoms and the patients go about their usual work thus exposing themselves to grave dangers Sometimes the only symptom observed is a rise in temperature lasting for about two days without any abnormal pulmonary signs In other cases the temperature is raised but the pulse is not quickened These masked forms of influenza of the ambulatory type are especially dangerous for the sufferer takes no care of himself and the influenza infection opens the door to infections of another kind so that the organism is very subject to the danger of invasion by the bacilli of pneumonia or the staphylococci or streptococci for which Pfeiffer's bacillus prepares the ground and the virulence of which it intensifies In time of influenza, then, preventive measures should be taken, antisepsis and asepsis of the body cavities should be used antiseptic lotions should be used for the mouth, the nose, and the throat, and blistering agents should be avoided as opening the door to infection For intestinal antisepsis reliance should be placed on a milk diet, which is preferable to medicinal antiseptics, it also acts favourably on the liver and kidneys Quinine should be given in large doses in the form of the bromohydrate and as much as nearly 19 grains (1 25 grammes) may be given if there is fever, and if not from seven and a half to 11 grains (0 5 to 0 75 of a gramme) may be given both as curative and preventive 10 centigrammes (one and a half grains) of the watery extract of ergot, and the same quantity of bromohydrate of quinine may also be given in the form of a pill, and 10 of these may be taken per diem Where nervous symptoms are marked glycero phosphate of lime, or still better strychnine sulphate, may be given Antipyrin should be used very sparingly and with the greatest care, or, better, not at all —M Hayem did not recommend milk It was a depressing diet and influenza was a very weakening complaint He could not understand M Huchard recommending this to relieve the digestive organs and at the same time recommending ergot and quinine, which were both digestive irritants —M Laborde agreed that antiseptic lotions for the nose and throat should be used He recommended a solution of carbolic acid of the strength of 1 in 200

The Treatment of Tuberculous Infection by Muscle Plasma

At the meeting of the Academy of Sciences held on Feb 26th M Héricourt and Professor Charles Richet made a communication as to the results of their researches into the mechanism of the action of the therapeutics of raw meat in cases of tuberculosis Cooked meat does not produce the same effect because cooking coagulates certain albuminoid ferments The important point, however, of the researches of these two observers is as concerns the active part of the meat They separated the pulp from the muscle plasma and have discovered that the plasma alone is active It is the principles which are soluble in water that constitute the active portion of the meat The question is not one of feeding or of over feeding, for the quantity of nitrogen contained in the plasma is very small, but it possesses immunising qualities analogous to those of other animal products which are injected into the veins M Héricourt and Professor Richet propose to call this new method of treatment zomotherapy"

Appendicitis in Pregnant Women.

At a meeting of the Academy of Medicine held on March 6th M Pinard read a paper on a certain number of cases of appendicitis in pregnant women which had come under his observation The symptoms were from the beginning marked and persistent pain with muscular rigidity of the abdominal wall especially well marked on the right side There were also vomiting and high fever, which last never accompanies the ordinary vomiting of pregnancy Peritonitis in pregnancy is unknown except after rupture of the uterus so the diagnosis in these cases is comparatively easy It should, however be made as early as possible Appendicitis in pregnancy is always most grave, and surgical intervention must not be delayed M Pinard described various cases in which a successful result had been obtained, although the patients were almost *in extremis* when operated upon. The pregnancy went to full term in the usual way after the operation

ROME

(FROM OUR OWN CORRESPONDENT.)

THE LANCET *and Italy's Climatic Resources*

"LA diffusissima e autorevole rivista clinica di Londra" (the most widely circulated and authoritative clinical review of London) has, according to last night's *Tribuna*, devoted a long series of articles fortified by statistics to demonstrating Italy's advantages over her southern rivals as a winter residence for the weakly and the ailing Starting with the report of THE LANCET'S Special Commissioner on Palermo and referring to its other communications on the same theme the Roman journal expatiates over two columns on Italy's attractions climatic and other, and reminds her of the duty these attractions impose on her to the public as well as to herself Towards the discharge of that duty a beginning has been made by that great Sicilian sanatorium, as it calls the "Villa Igiea," with its 150 rooms specially appointed for the treatment of the phthisical and it proceeds to announce that yet another step has been taken in the direction indicated—the foundation of a hotel, also at Palermo, on the lines and on the scale of the princely "Alberghi" of Rome and under such skilled and effective management as those of Zurich or

Lucerne. So far so good. But, as THE LANCET has often shown, there are many other reforms to be introduced and drawbacks to be removed before Italy can reap the benefit she aims at from the institution of sanatoria or colossal hotels. Railway travelling has yet to be robbed of its terrors for the invalid—the "Flying Lombard" or the "Wild Tuscan" (top speed 35 miles an hour, with many an irritating halt between) being greatly deficient in the comfort and convenience ruling on British or American lines. Arrived at his destination with his valise unrifled the English-speaking invalid must not be threatened with the substitution of an Italian for a compatriot practitioner. The former may have all the virtues under heaven and often, indeed, enjoys a good share of them; but not even such "credentials" can overcome the Briton's or the American's partiality for a compatriot medical adviser, speaking his own language and trained to appreciate the national traditions, requirements, nay, prejudices, if you will. On this theme, a thrice-told tale in THE LANCET, I need not enlarge, except once more to assure your influential lay contemporary the *Tribuna* that the greatest bar to the development of that "Industria del Sole," as it appropriately call's Italy's utilisation of its genial climate, is precisely the Bill for the exclusion of the English-speaking practitioner associated with the name of Dr. Santini.

The Senator Lorenzo Bruno.

"He was a veray parfit, gentil knight." Chaucer's famous line depicts admirably the great surgeon, the accomplished lecturer, and the public-spirited philanthropist whom the sub-alpine capital, and, indeed, all Italy, lost on Sunday, March 4th, in his eightieth year. Hale and well-preserved in mind and body Professor Lorenzo Bruno, contrary to expectation, failed to rally from the attack of influenza which struck him down at the close of February. He was conscious, however, to the end, and when it came it found him ready, in the words of Horace—

> "Exacto contentus tempore, vitâ
> Cedere, uti conviva satur,"

with his family and his professional advisers (some of them old pupils) around him. Born on July 26th, 1821, near Mondovì, his father was an eminent practitioner who as the parent of 12 sons was exempted (*affrancato*) from all fiscal burdens and who therefore gave the name of "Franco" to the youngest, now one of the lights of the Turinese bar. Lorenzo chose his father's profession and qualified in medicine and surgery at the Sub-alpine University, whence, after holding with distinction several clinical posts, he became in 1848 "Medico degli Ospedali Militari." In the campaign against Austria in 1859 he won the highest praise, particularly from his colleagues in the French lines of the allied army, for the success that almost invariably attended his operations (some of them extremely difficult), and when in 1862 the Turin chair of surgery lost its illustrious occupant Riberi, Lorenzo Bruno was at once chosen to fill it. King Victor Emanuel, who had witnessed his skill in operation, his judgment in treatment, and his serene courage under fire, now attached him to the royal person, in which capacity he accompanied His Majesty on the memorable visits to Vienna and to Berlin. Frequently associated with the "Rè Galantuomo" in his Alpine sports, especially in the summer quarters at Valsavaranche and Cogne for shooting the chamois and steinbock, Professor Bruno became his confidant even in delicate State affairs and by royal decree of Nov. 17th, 1876, was nominated Senator of the Italian Kingdom—an honour which the King was careful to be the first to announce to him. Meanwhile his work in professorial chair and clinical ward never relaxed, his classes steadily rose in numbers and enthusiasm, and when from dean of the teaching staff he rose to be Rector Magnificus of the University the appointment was unanimously hailed as of the best augury for the interests of the sub-alpine school. President for many years of the Royal Accademia della Medicina he gave a high direction and tone to its proceedings and contributed to the "Atti" a large number of papers independent in judgment and research, while easy yet chastened in style. His funeral on March 6th was one of the most impressive ever witnessed in the Piedmontese capital.

How the "Rè Galantuomo" Died.

Early in the winter of 1878 King Victor Emanuel, then an inmate of the Quirinal Palace in Rome, fell ill of pneumonia and Lorenzo Bruno was not the least
trusted among the eminent consultants who from
to day met around his bedside. It was he, in fact,
was deputed to convey to His Majesty that medi
was no longer of any avail and that the end was but a
hours off. The interview between the royal patient and
"beloved physician," now for the first time made public,
besides its historical interest, a special value for the lig
throws on the character of the two men. "Sire," said Br
"the mention of danger to a prince of the House of S
entails no embarrassment, for danger is his *métier*. All
Majesty's forefathers have, when their lives were in
balance, been willing to approach their God. I am sure
is your Majesty's desire." For a moment a cloud see
to rest on the King's countenance and he asked, "
I then so ill?" Bruno replied, "We have not g
up all hope; but it is always well to make every prep
tion." The King then raised his hand to his forehead
said, "Very well; send for Anzino" (the court chap
and almoner). Monsignor Anzino came from an adjoi
room, received His Majesty's confession, and at its c
saw the King put his arm round Bruno's neck, with
words, "I know you have always wished me well;
now I understand that you are my true friend." Ha
known from Bruno that the King was sinking
Anzino drove off to the church of SS. Vincenzo
Anastasio for the viaticum and hastily enclosed
in a case which he concealed in his vestments. Arri
at the Quirinal he made haste to collect some can
from the chandeliers in an ante-camera and having di
buted them among those present improvised in this mar
a suitable accompaniment to the "Santissimo."
Majesty then partook of the holy eucharist, whereupon
the Court, according to the usage of the House of Sa
passed one by one before the dying King who, having ra
himself in bed, fixed on each a glance of his still lust
eyes, after which he fell back on the pillow and in a
minutes expired.

March 11th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The Bubonic Plague.

IN a previous communication reference was made
the outbreak of bubonic plague at Noumea and to
fear of the health authorities that the disease wo
reach Australia. This fear has proved well grounc
as cases of bubonic plague have occurred in both A
laide and Sydney. The Adelaide cases are pecu
and some of the profession doubt the correctness of
diagnosis A seaman absconded from the ship *Form*
from New York to Port Adelaide, six weeks bef
his death in the Adelaide Hospital on Jan. 12th after
illness of 26 days' duration. The diagnosis of his dise
as plague was made post mortem. The second c
occurred in a boy, aged nine years, who came from the to
where the first patient had been staying prior to his adn
sion to hospital. This boy has so far recovered. The So
Australian branch of the British Medical Association as
the Government to have an inquiry made by an exp
from another colony into the alleged outbreak, but
action has yet been taken. The old quarrel in connex
with the Adelaide Hospital has been revived by this incide
It will be remembered that Dr. Ramsay Smith was brou
out by the Government to act as physician to
Adelaide Hospital when the local members of the p
fession refused to act. Dr. Ramsay Smith was subsequen
appointed chairman of the Board of Health and in
capacity declared that the two cases were bubo
plague. In consequence Adelaide has been proclain
an infected town and all passengers from the proclain
city are examined by specially appointed medical offic
at the border and the ports before being allowed
enter the other colonies, and the mail steamers have cea
to call at Adelaide The reasons for casting doubt on
diagnosis are that the ship *Formosa* came straight from N
York without touching at any plague-infected port, t
there was no illness on board and no other cases h
developed among her crew, and the long time (six wee
the alleged case was in the colony before the dise
developed. The man was in a most filthy condition
further cases have occurred in Adelaide and the local Bo

of Health there has also resolved that the Government should appoint an independent Commission to inquire into the outbreak. In discussing the subject the feeling was generally expressed that the cases were not genuine plague. In all the Australian cities stringent precautions have been taken to prevent the entrance of the disease and extra attention given to enforcing sanitary conditions. In Victoria some amendments to the Health Act are being drafted by the Board of Public Health giving greater powers of inspection to health officers, of isolation of suspects, and for ordering the cremation of any body dead from an exotic disease. The Sydney authorities were very sceptical about the existence of the plague at Adelaide, but were soon compelled to take measures against the disease in their own city. On Jan. 24th a case was reported to the Board of Health as suspicious, and the patient, a ship's carter, and all the occupants of his house were removed to the quarantine station and the patient's house was isolated and disinfected. Upon further observation the case was pronounced to be a mild one of genuine bubonic plague, and the infection was believed to be by a flea-bite. The locality where the patient lived is a shipping one, much visited by sailors and infested by rats, and the authorities believe that the disease was introduced by inoculated rats. No further cases have occurred in Adelaide or Sydney and the restrictions on inter-colonial traffic have been removed.

Annual Meeting of the Medical Society of Victoria.

The annual meeting of the Medical Society of Victoria was held on Jan 10th, the retiring President, Sir T. N. Fitz-Gerald, being in the chair. The report of the committee showed that the work of the past year had been very satisfactory. The following were elected office-bearers for 1900:—President: Dr. J. W. Barrett Vice-Presidents: Dr. D Grant and Dr. C. J. Martin. Honorary treasurer: Mr. C H. Mollison. Honorary secretary: Dr. E L Gault. Honorary librarians: Mr. A. W. F. Noyes and Dr. J. S. Buchanan. Committee: Mr. F. D. Bird, Dr. W. Boyd, Dr. D. A. Gresswell, Dr. G. T. Howard, Mr. A. L. Kenny, Dr. H. Maudsley, Mr. W. Moore, Mr. Hamilton Russell, Dr. R R. Stawell, and Dr. A. J. Wood. The retiring President delivered an interesting address reminiscent of the changes that had occurred during the 20 years since he occupied the same position as President and the preceding 20 years which separated him from his student days. Would such changes ever occur again? he asked. Should they ever again go through such a period of unlearning and of relinquishing of beliefs? Although a surgeon he considered greater scientific advances had been made towards the benefit of mankind by bacteriological studies than by the surgeon's knife. Surgery too often strutted in borrowed plumes and the supposed triumphs of the operating theatre were really due to the application of the work of the laboratory. Sir Thomas Fitz Gerald contrasted the medical and surgical work of the past with that of the present, illustrated by many personal anecdotes and experiences.

The Health of Sydney.

The report of Dr. M. Kendall, medical adviser to the Water and Sewerage Board of Sydney for the past year, shows a marked increase in fatal cases of typhoid fever, 173 persons dying from that disease, more than double the usual mortality. Dr. Kendall seems to blame the municipal arrangements for the insanitary conditions prevailing in some of the quarters where typhoid fever has been most fatal. The city health officer furnished a report to the City Council on the health of the city, in which he stated that the total death-rate had not increased and the number of cases of infectious disease of all kinds reported was less than usual. Typhoid fever had prevailed in low-lying areas which he reported in 1892 as unhealthy—due to the recklessness of speculative builders in erecting dwellings at such levels as rendered drainage impracticable. The Mayor admitted that the monthly reports of the city health officer had been systematically shelved and ignored by the City Council. The council appointed four additional sanitary inspectors.

New South Wales Army Medical Corps sent to South Africa.

In November, 1899, the New South Wales Government despatched to the war in South Africa a field hospital and a half bearer company, with eight medical officers and the necessary transport equipment. Since then the Imperial Government has cabled a request that the other half of the New South Wales Army Medical Corps with its complete equipment should be sent to the front. This half unit left on Jan. 17th, under the command of Lieutenant-Colonel Kelly. The other officers of the corps are Captain W. L. C. Eames, Captain G. A. Marshall, Captain J. Marshall, Lieutenant Newmarch, Lieutenant Samuelson, and Lieutenant Dick. In addition, a number of medical practitioners volunteered for service, and the offers of Dr A. MacCormick, Dr. Scot Skirving, Dr. Cortis, Dr. N. Howse, and Dr. Horsfall were accepted. A company of 14 trained nurses also left with the Army Medical Corps.

Jan. 24th.

Obituary.

WILLIAM MARCET, M.D. EDIN., F.R.C.P. LOND., F.R.S.

DR. WILLIAM MARCET, whose death we have already announced as occurring on March 4th at Luxor, was born in 1828 at Geneva, where he was educated in his early days. His father was Professor Francis Marcet and his grandfather was Dr. Alexander Marcet of Guy's Hospital, whose wife was Jane Marcet, the well-known authoress. When 18 years of age William Marcet entered at the University of Edinburgh, being a contemporary of William Priestley, John Burdon Sanderson, and Charles Murchison. In 1850 he graduated as Doctor of Medicine and came to London, where he at first interested himself chiefly in researches into physiological chemistry. As a result he was elected a Fellow of the Royal Society on June 11th, 1857. He was also for some time assistant physician to the Hospital for Consumption at Brompton and also to the Westminster Hospital. As became one born in Geneva, he was greatly attached to mountains and made a number of researches into the influence of high altitudes upon respiration. He commenced his inquiries in 1876 and continued them during his residence in the High Alps every summer until 1880. A laboratory having been placed at his disposal by the kindness of Professor Schafer at University College, London, experiments and researches were regularly continued by himself and his assistants from the year 1883 up to 1895 and afterwards up to February, 1899. He appears to have been induced to undertake this work by his experiments on the composition of expired air and the results of decrease of pressure made in the high Alps in "the seventies," and in 1887 he commenced his inquiries which were destined to terminate in such valuable additions to our knowledge of respiratory phenomena. The points successively established were the following: (1) confirmation of the quantity of carbonic acid expired per minute under various conditions; and (2) quantity of oxygen retained in the blood under various conditions. These two points were discussed and elaborated in the Croonian Lectures. Following upon these came (1) the measurement of the quantity of heat given out by the human body for one gramme of oxygen absorbed; and (2) the efficiency of the human machine. Those who worked with Dr. Marcet during this inquiry (he always had the assistance of a young chemist) know with what perseverance he applied himself to the work, never resting content unless he saw every detail of the work and confirming every questionable point with repeated experiment. In the chemical work of this inquiry he showed that Pettenkofer's method is the most reliable for the estimation of carbonic acid; although he tried many volumetric methods he was always forced to reject them. He perfected a form of eudiometer for the estimation of oxygen in expired air, with this instrument two determinations to the second place of decimals in percentage of oxygen could frequently be made, and he devised a calorimeter for the measurement of the heat given out by the body. In his final experiments it will therefore be seen that the chemical labours were not small—the accurate determination of carbonic acid and oxygen in air expired in the calorimeter at rest and while work was being done, and the measurement of the heat given out on both these occasions, involved rigorous analytical operations. The outcome of all this work was the Croonian Lectures upon Respiration which Dr. Marcet delivered before the Royal College of Physicians of London in 1895.

Another subject to which he devoted attention was that of climatology, and in 1883 he published a book upon the principal southern and Swiss health resorts, while in 1877 he had written for the *Quarterly Journal of the Meteorological Society* a paper on the Meteorology of Cannes.

He was President of the Royal Meteorological Society from 1888 to 1889. Another matter in which he did good work was the influence of alcohol upon the human organism, especially in regard to the effect of alcohol upon the nervous system, and in 1860 he published a book dealing with the point.

In the Croonian Lectures, which formed one of the most important contributions ever made to the subject in hand, the history of the respiration was fully gone into. In the first lecture the oxygen of the atmosphere was shown to be the main agent of life and Hermann's discovery that oxygen is an integral part of the tissues was appealed to as a mode of explanation of the remarkable tenacity of life shown by certain tissues—such, for instance, as seeds. It was then demonstrated that it is not oxygen which produces metabolism, but that the living tissues themselves call upon the oxygen to effect the changes which they undergo. This was demonstrated by the action of cold which when not excessive increases the vitality of the tissues and consequently their demand for oxygen. The second lecture dealt with past investigations on respiration, and the different forms of breathing were illustrated by tracings. Oxygen was shown to be absorbed by the body independently of the formation of carbonic acid and analyses were quoted to show to what extent such absorption takes place. The third lecture dealt entirely with the influence of volition upon respiration. Volition towards any kind of muscular exercise, including forced breathing, is attended by absorption of oxygen in excess. This oxygen is necessary to the performance of volition, and if necessary to volition must be taken up by the motor centres of volition. The effects on the development of muscular force by this charging of the centres for motion with oxygen were discussed and an experiment was described showing that where volition became tired out the muscles refused to work. The last lecture dealt with the phenomena of respiration at high altitudes and with the effects of re-breathing and of breathing air under pressure. It was also shown that the effects of re-breathed air were not due so much to the absorption of carbonic acid as to the want of oxygen. Finally, the treatment of asthma as suggested by the considerations put forth in the lectures was discussed. Not the least valuable of Dr. Marcet's researches was that in which he was engaged during the cattle plague. The Royal Commission which was appointed in 1865 to inquire into the matter enlisted the services of various scientific men as experts in different fields of science, and to Dr. Marcet fell the part of reporting upon the chemistry of the blood and tissues and the value of disinfectants. *His report,* together with those of the other experts, among whom were Dr. Murchison, Dr. (now Sir) John Burdon Sanderson, and Dr. Bristowe, appeared as an appendix to the third report of the Commissioners which was published in 1866.

WILLIAM ADAMS, F.R.C.S.ENG.

WILLIAM ADAMS, who died on Feb. 3rd last at an advanced age, was for a long time the best-known orthopædic surgeon in England. He joined the medical school at St. Thomas's Hospital in 1838, at which time the surgeons of the hospital were Benjamin Travers, Joseph Henry Green, and Tyrrell. He was Green's pupil and to the end of his days cherished feelings of the sincerest admiration for his able teacher; but most of his anatomy and physiology was done at Grainger's in the Webb street School in Maze Pond, Southwark. (It will be remembered that the ancient site of St. Thomas's Hospital was in Southwark.) In 1842 William Adams became a Member of the Royal College of Surgeons of England, and his anatomical and pathological work was so well known to his superiors that immediately he was qualified he was appointed curator of the museum and demonstrator of morbid anatomy at St. Thomas's Hospital. In the same year, that is, in 1842, St. Thomas's Hospital purchased Grainger's School, and Richard Grainger became Adams's colleague as demonstrator of physiology in the hospital. In taking over Grainger's School St. Thomas's Hospital acquired the services of one Tom Parker, the dead-house assistant, who was a noted resurrectionist, and the stories that he told to his new master of the practices in which he had been engaged were certainly thrilling, and to the end of his days Mr. Adams loved to detail them to younger generations of medical men to whom "body-snatching" was only a word. One such story will be found in Dr. Sprigge's "Life and Times of Thomas Wakley" on page 49, and goes to prove that Tom Parker was probably the man who decapitated Thistlewood upon the scaffold—a gruesome act which in an indirect way led to the founding of THE LANCET.

Adams was for 12 years lecturer on morbid anatomy at St. Thomas's Hospital Medical School, and in 1851 he became a Fellow of the Royal College of Surgeons of England. Three years later he joined the Grosvenor place Medical School, adjoining St. George's Hospital, as lecturer on surgery and hospital practice, his fellow lecturer being Mr., afterwards Sir T. Spencer Wells. At the Grosvenor-place School he first showed his tendency to specialise in orthopædic surgery, for he delivered there several courses of lectures on this subject and became at the same time surgeon to the Royal Orthopædic Hospital. He also wrote about this time a sketch of the Principles and Practice of Subcutaneous Surgery and an essay on the Reparative Process in Human Tendons after Subcutaneous Division for Cure of Deformities. In 1864 Mr. Adams carried off the Jacksonian Prize of the Royal College of Surgeons of England, his essay being entitled, "Club Foot, its Causes, Pathology, and Treatment." A second edition of this book was published some ten years later and the work may be said to register all the surgical knowledge of its day upon the subject. He was appointed surgeon to the Great Northern Central Hospital and to the National Hospital for the Paralysed and Epileptic. In the latter institution his work was mainly orthopedic, for the day of cerebral surgery had not arrived, but at the Great Northern Central Hospital he did capital general surgery. It was here that he devised the operation generally known by his name, viz., osteotomy for ankylosis of the hip-joint, the neck of the femur being divided subcutaneously within the capsule. For this operation he invented a special saw and laid down a complete procedure designed to prevent the admission of air to the joint—a matter upon which antiseptic surgeons of the present day have not to be so particular. Among his written contributions to the knowledge of his profession may be mentioned the Lettsomian Lectures delivered before the Medical Society of London in 1869 on Rheumatic and Strumous Diseases of the Joints, including Hip-joint Disease—this particularly as showing that Mr. Adams was not a one-ideaed man although his name is so generally identified with orthopædic surgery—and essays on Congenital Contraction of the Fingers, on Hammer-toe, and on Congenital Wry-neck.

*Up to 1896 Mr. Adams continued to reside in Henrietta-*street and until late in life enjoyed a large practice. But four years ago he definitely decided to cease from work and retired to a house in Hampstead where he died in the first week in February in the eightieth year of his age. He had outlived most of his contemporaries and professional friends, but there are still some left to testify to the high position which William Adams occupied for very many years of his professional life. He was a sound pathologist and a dexterous surgeon and his operative procedures were dictated by intimate knowledge. In private life he was a most genial and humorous man, hospitable, exceedingly kind, and a voluminous talker.

Medical News.

UNIVERSITY OF CAMBRIDGE.—As Professor Watson Cheyne and Professor Chiene are absent on war service in South Africa Professor E. Ward of Leeds and Mr. G. E. Wherry have been appointed to examine in surgery at the next M.B. and B.C. Examination. At a special congregation on March 10th the following were admitted to medical and surgical degrees:—

M.B. and B.C.—R. F. C. Ward, B.A., St. John's; C. L. Hawkins, M.A., Emmanuel, F. W. Curl, M.A., Downing; A. E. Martin, M.A., Downing.
B.C. only—W. B. Winton, M.A., Clare.

The estimated cost of the new medical school buildings, which are to accommodate medicine, surgery, midwifery, medical jurisprudence, public health, pharmacology, and pathology, is some £35,000. The Syndicate propose that the museum of the school, which has been made a prominent architectural feature in the plans, shall be named the

Humphry Museum in commemoration of the services rendered to the university by the late Sir George Murray Humphry As it is doubtful whether more than £15 000 can be raised from local sources for the erection of the buildings there is ample room for further large benefactions The Syndicate report that there are now over 450 medical students in Cambridge, the average annual entry being 140 and that the present buildings are not only inadequate in extent and equipment but are irreparably dilapidated The professors and other teachers with their friends have contributed liberally to the building fund but the ability of the University to supplement their efforts as they deserve is more than doubtful

LOUGHBOROUGH GENERAL HOSPITAL The annual meeting of the governors and subscribers of the Loughborough General Hospital was held on March 12th, Mr Hussey Packe presiding The balance sheet showed a deficit of £101, mainly owing to expenditure on alterations and repairs, the total expenditure being £1521 16s 7d During the year 843 out patients received medical treatment and 593 received surgical treatment whilst 44 patients were admitted for medical treatment in the institution and 134 for surgical, no less than 600 casualties being dealt with The annual subscriptions were the highest ever received in a year The reports were adopted Mr Hussey Packe was re-elected president Votes of thanks to the honorary medical staff, committee, and visitors, concluded the meeting

PRESENTATIONS TO MEDICAL MEN —On Feb 22nd Mr T B G Stableford, M R C S Eng , L R C P Lond , of Whitchurch, Glamorganshire, being about to proceed on active service to the seat of war in South Africa, was the recipient of useful and valuable presents from friends as tokens of friendship and esteem —On Feb 28th the members of the Shepherds on the Down Lodge of Ancient Shepherds presented Mr E F Hastings Burroughs, L R C S Irel L A H Dub , of Redland Bristol, with a marble timepiece and also with a silk sash having the arms of the society woven on it as a mark of appreciation for his faithful services as lodge surgeon —Mr A H McDougall L R C P Lond , M R C S Eng, district medical officer, parish of Birmingham, who is going to the front in South Africa, was presented on taking leave of his colleagues on March 6th with several mementoes of his association with the parochial offices

LITERARY INTELLIGENCE —Messrs Baillière, Tindall and Cox announce the publication next week of the following important works —A second edition of Mr Mayo Robson's "Diseases of the Gall bladder and Bile Ducts very considerably enlarged and with many new cases added An English edition of Dr Macnaughton Jones's Manual of Diseases of Women The form of this edition has been changed from a crown 8vo to a demy 8vo and is to contain about 1000 pages more than 600 illustrations, and 28 plates It has been almost entirely re written and many new illustrations have been added A translation of Dr José Montenegro's "Bubonic Plague' by Dr William Munro with an appendix specially written by the author *for the English edition* 'Mock Nurses of the Latest Fashion,' by Mr F J Gant, reprinted with additions from the *Medical Press* The object the author had in mind when writing this series of sketches drawn from his personal experience was the advisability of "registration of nurses' There will also be published very shortly by the same firm a translation of Dr Ludwig Grünwald's important work on "Nasal Suppuration, and two more volumes of the recently started Medical Monograph Series, entitled, "Bacteriology of Everyday Life ' by Dr J O Symes and "Appendicitis ' by Mr A H Tubby

DEATH OF A CENTENARIAN —The *Torquay Times* of March 2nd announced that Mrs Mary Susan Curtis died at No 20 Sanford crescent Cockington Devonshire, on Feb 26th, at the remarkable age of 102 years and nine months She was the daughter of Robert and Sarah Clamp and was born in the parish of St Nicholas Ipswich, on May 27th 1797 According to the registers of the parish she was baptized on July 23rd 1797 She was married at the same church on March 12th 1820 to Mr George Curtis of St Lawrence She had been a widow for 33 years, her husband having died in 1867 Mrs Curtis was aunt to Sir Alfred Garrod M D Lond Her sight and memory were fairly good, and she enjoyed reading the daily paper Long after she had passed her hundredth year she was to be seen walking in the neighbourhood of the avenues and the pier Mrs Curtis celebrated her centenary on May 27th, 1897, at the then residence of her daughter, Mrs Cockrill, Victoria parade when she was surrounded by her children grandchildren, great grandchildren and other relatives Until the attack of bronchitis which terminated fatally in five days, Mrs Curtis had been remarkably free from illness having only required medical attendance for accidents during the last four years In January, 1896 she fell and wounded her forehead very badly, but the wound healed by first intention Last October she fell down two steps and severely wounded her left arm from the shoulder to the elbow, but made a good recovery

OXFORD UNIVERSITY —The degree of M A (*honoris causâ*) was conferred in Convocation on Feb 27th upon Alexander Frederick Bradshaw, C B , M R C P Lond , Surgeon Major General (retired) honorary physician to the Queen, Fellow Commoner of Worcester College

THE LATE SURGEON B G HEATHER, R N —The funeral of the late Surgeon B G Heather, R N , whose death was announced in THE LANCET last week took place on March 7th at Plymouth Cemetery The *cortege* which left the Naval Hospital was headed by a funeral escort of over 100 men of the Royal Marines with the full band of the regiment Six naval surgeons acted as pall bearers There were also present many officers and a number of retired officers and men The cause of Mr Heather's death was influenza followed by Malta fever Much sympathy is felt in Plymouth for his father, Captain Heather, R N

THE LATE MR E STEPHENS – Mr Edward Stephens of Ilminster Somerset died on March 8th, in his fifty fourth year Mr Stephens received his medical education at Liverpool and University College and St Mary's Hospitals, London and took the qualifications of M R C S Eng, and L R C P Edin in 1868 and 1869 respectively He commenced practice in Ilminster about 30 years ago and at the time of his death was medical officer of health for the Chard rural district and medical officer and public vaccinator for the Ilminster district of the Chard Union Mr Stephens, who had lately been in indifferent health had gone on a visit to Bromley, Kent and died there The deceased will be much missed in Ilminster where he was very popular, especially amongst the poor, to whom he was most kind

NOTES ON CURRENT TOPICS

Lunacy Bill

THE Bill to amend the Lunacy Laws promoted by the Government has passed through all its stages in the House of Lords and now falls to be dealt with by the other branch of the Legislature

The Midwives Bill in the House of Lords

The Midwives Bill introduced into the House of Lords by Lord GLENESK was put down for second reading on Tuesday March 13th It was not however taken on that date, and it is understood that it has been indefinitely postponed

HOUSE OF LORDS

THURSDAY MARCH 8TH

War Clothing for the Troops in South Africa

The Marquis of LANSDOWNE made an interesting statement on this subject, which had been brought to the notice of the House by the Earl of LEVEN AND MELVILLE His lordship gave a description of the principal articles in the soldier's wardrobe He said In the first place there is his fighting suit That as the House knows is made of what we commonly call khaki—a word which, for the rest describes the colour and not the material The khaki clothing which until the present campaign has been issued to the Army has been cotton khaki commonly called khaki drill Of that khaki drill two suits have usually been issued to each soldier besides the ordinary clothing for campaigning purposes We are substituting for one of these suits a suit of khaki woollen serge which is obviously much more suitable to the climate Of these khaki serge suits 140 000 have been sent out, either with the men as they embarked or so as to follow them That number ought to provide one suit for every man who has already started for South Africa In addition to that we hope to send out weekly consignments of from 10,000 to 15,000 suits of khaki serge I am a little uncertain as to the exact number because in this matter we are to a certain extent in the hands of the contractors there are very few of them who are able to produce material of the quality which we require Then, as regards shirts, each man takes out with him two flanne hirts. Besides these we have sent out 96,000, and we hope to go on ending them out at the rate of about 25,000 per week. Each man has woollen jersey as part of his kit. We have already sent out 42,000 nore to meet additional requirements, and we hope to send out jerseys t the rate of 20,000 a week. Then each man has two flannel belts to tart with. We have sent out 40,000 more and expect to be able to send ut others at the rate of 50,000 a week during the next few weeks. We re also sending out weekly a consignment of 50,000 pairs of woollen socks, nd 330,000 pairs have already gone out. We have sent out 26,000 great oats, and hope to send out from 3000 to 8000 a week to replace those hich originally went out with the men, and no doubt are beginning o show signs of wear. Then we shall send 10 000 woollen caps eekly to replace the woollen caps which went out with the men. I nay also mention that in this campaign we have for the first time nade an issue to the dismounted troops of woollen drawers. Hitherto, believe, it has been customary to give cotton drawers only, and these nly to the mounted men. Before the cold weather sets in in South frica we shall issue two pairs of woollen drawers to the whole of the ismounted troops; 200,000 pairs have already gone, and it is hoped to end out 20,000 pairs a week. The only other matter which I need otice is that of blankets. Each man took out two blankets with him. Ve have sent out 166,000 more, and we are continuing to send them out t the rate of 30 000 a month. Of course, I need not tell your lordships hat these articles of clothing are issued quite irrespectively of those hich the great generosity of the public has in many cases supplied to ie troops.

MONDAY, MARCH 12TH.

The Provision for Invalid Soldiers.

Earl **CARRINGTON** addressed a question to the Secretary of State for Var with reference to the provision made for invalid soldiers on eaving Netley Hospital.—The Marquis of **LANSDOWNE**, in the course f his reply, said that the result of inquiry led him to think hat the arrangements for supplying clothing to invalid soldiers vhen they left hospital required further consideration, and he vas glad to be able to say that attention was being given to his matter some days before the noble earl called attention to he subject. It had been settled that the principal medical officer at Netley should be instructed that whenever an invalid soldier was bout to leave hospital, he was to communicate with the depôt of the egiment to which the man belonged, and from thence receive any lothing belonging to the man which might have been left there, or new lothing which the man could wear on the journey from the hospital o the station where the regiment was quartered, and in a case where man was going to a convalescent home it was proposed to give him, n addition to his usual clothing, hospital clothes which he could wear n the home. He took this opportunity of expressing acknowledgment o the many benevolent persons who had offered houses of all descriptions—he might almost say from cottages to palaces—as convalescent iomes for invalid soldiers. His only regret was that he did not see a prospect of filling them all. He was told that the private soldier when lischarged from hospital very much preferred going to his own home han to a convalescent home, however comfortable or luxurious. Nevertheless, the service was under a great obligation to those persons who, at great trouble and inconvenience, had made these generous offers.

HOUSE OF COMMONS.

THURSDAY, MARCH 8TH.

The Food of the Royal Navy.

While the House was in Committee of Supply on the Navy Estimates several members called attention to the food supplied to the bluejackets and marines. They complained particularly of inadequacy in the case of the breakfast which is taken very early in the morning, and consists of a pint of tea or cocoa and dry bread or biscuit, and they asked for a departmental committee to inquire into the subject.—Mr. **GOCHEN**, in reply, said that the subject must be considered in connexion with the system of canteens which had been greatly improved in recent years. However, he undertook to confer with his naval colleagues as to the propriety of instituting a departmental inquiry.

FRIDAY, MARCH 9TH.

Women and Children in Textile Factories.

Sir **CHARLES DILKE** asked the Home Secretary what had been the result of further inquiry into the recent illegal working of women over hours in textile factories having contracts for the War Office; whether it had been found that the Bradford Trades Council were justified in their statement that the absence of inspection had allowed manufacturers working illegal overtime not only to produce cloth for Government purposes but also for private sale; and whether, as stated, firms who could have executed the orders without illegal overtime had been passed over, and in the course of last week not only women but also children had been illegally working overtime.—Sir **MATTHEW WHITE RIDLEY** replied: Individual inquiries have been made with regard to all firms known to be working overtime on Government contracts. In a few cases it was found that the overtime had been used for private work, and this has been stopped. In one case children were found to be employed overtime, and this also has been stopped. The names have been supplied to me to-day by the right hon. baronet of some firms who appear to be working overtime without the knowledge of the factory inspectors. I will make inquiry into these and take such action as the circumstances may call for. As regards the first sentence of the last paragraph of the question, I can only repeat that the selection of firms for these Government contracts is not a matter as to which I have any responsibility or information.

Salt Beef Rations for the Troops.

The supply by the Admiralty of beef pickled in 1893 to one of the transports taking troops to South Africa was raised again at this sitting of the House and Mr. **MACARTNEY**, Financial Secretary to the Admiralty, after explaining the circumstances in which the issue took place, intimated that the whole question of salt beef rations is now under the consideration of the Admiralty with a view of seeing whether measures ought to be taken to diminish the amount of these rations.

The Sale of Intoxicating Liquor to Children.

The House gave a second reading to a Bill which raises the age for the sale of intoxicating liquor to children to 16 years.

Medical School of Queen's College, Cork.

Mr. **JOHN REDMOND** asked the Chief Secretary to the Lord Lieutenant of Ireland whether, in view of the fact that there was only one Roman Catholic professor in the medical school of the Queen's College, Cork, it was intended to appoint a Roman Catholic to the professorship now vacant, and whether it was intended that this appointment should be filled by a physician as in the case of every other medical school in the United Kingdom. The **ATTORNEY-GENERAL for IRELAND** (Mr. Atkinson), who replied for the Chief Secretary, said: I have no information as to the religious denominations of the occupants of the medical chairs in the Queen's College, Cork. As regards the remainder of the question I can only say that the legitimate claims of all candidates for the vacant chair will be fully considered.

MONDAY, MARCH 12TH.

Rabies in Ireland.

Mr. **HORACE PLUNKETT**, replying to a question addressed to him by Dr **TANNER**, said that 18 authenticated cases of rabies were reported from the whole of Ireland during the six months ended Feb 28th. and of these eight cases occurred during the past three months. Toxic results were demonstrated in 11 out of the 18 cases. The diagnosis of rabies in all of these cases was founded either upon experimental investigation by what is known as the Pasteur inoculation method or where such investigation was not practicable upon the results of careful inquiries made at the place of outbreak by qualified veterinary Inspectors.

French Assistance for the Wounded in South Africa.

Mr. **HAZELL** asked the Under Secretary of State for War whether he was aware that the French Society for affording Aid to the Wounded had sent from Paris 45 cases of instruments, medicaments, and other useful articles for the use of our hospitals in the front in South Africa, and, if so, whether some public recognition would be accorded to the society for its gifts.—Mr. **POWELL WILLIAMS** replied for the Under Secretary, saying: Yes, sir, Lord Wantage, the chairman of the Central British Red Cross Committee, accepted the offer in fitting terms and notified the gift to the public press at the time.

The Ambulance Wagons at the Front.

Mr. **HEDDERWICK** asked the Under Secretary of State for War if his attention had been called to the statement that the ambulance wagons attached to our forces in the field were in many respects inferior to those of the Boers, and whether the British ambulance wagons were without springs and in consequence were liable to jolt considerably, were so heavy in their build as to require 10 mules to draw one wagon, and were so constructed as to provide accommodation for only two wounded men in a recumbent position in each wagon as against eight in the case of the Boer wagon; and, if so, whether he would consider the propriety of taking steps to secure in future an ambulance wagon of a design better adapted for the requirements of the field and less likely to inflict unnecessary pain upon wounded men.—Mr. **POWELL WILLIAMS** replied for the Under Secretary of State for War, saying: The British ambulance wagon has excellent springs and in the Long Valley at Aldershot it can be drawn by a pair of horses. It accommodates either two men on stretchers and four seated or 12 seated It contrasts favourably with any ambulance wagon of a European nation. Nothing is known of the construction of the Boer wagons No complaints have been received at the War Office from South Africa.

The Teeth of Navy Recruits.

Mr. **WEIR** asked the First Lord of the Admiralty whether he could state the percentage of men and boys recruited for the Royal Navy who were rejected on account of bad teeth.—Mr. **GOSCHEN** said that the Admiralty had no statistics as to the percentage, but it was large; it might be as much as 25 per cent. Careful attention had to be given to the teeth of candidates as a test of health and suitability for service afloat.

TUESDAY, MARCH 13TH.

Vaccination Question.

Mr. **THOMAS BAYLEY** asked the Under Secretary of State for War whether his attention had been called to the death of Joseph Donovan, a private in the King's Own Yorkshire Light Infantry who, according to the finding of a coroner's inquest at Derby on March 3rd, died on Feb. 11th from pneumonia, secondary to pemphigus following vaccination; whether, in view of the fact that another soldier at Pontefract suffered during the same month from this rare disease supervening on vaccination, he would cause a strict investigation to be made into the source of the lymph used, in accordance with the recommendation of the jury; and whether he would advise that compensation be paid to the deceased's widowed mother on account of the loss of her son.—Mr. **POWELL WILLIAMS** replied to the question, saying: Yes, sir, there were three in all, two of which proved fatal. A careful inquiry is being made into these cases. The lymph used was from three different calves and from these same calves lymph was used in the vaccination of over 15,000 cases without any other unfavourable reports. No award from army funds can be granted as compensation, but if the man's mother was dependent on him for support the Patriotic Fund will be able to help her.

THE MIDWIVES BILL.

SECOND READING PASSED, MARCH 9TH.

The circumstances of the Midwives Question regarded from the Parliamentary point of view have undergone a sudden, unexpected, and substantial change As our readers are aware the Bill was introduced in the House of Commons early in the session by Mr. **TATTON EGERTON** who got for its second reading the second place in the list of orders for Wednesday, Feb. 28th. The first place in this list was held by the Miners' Eight Hours Bill and, as was expected, the discussion of this measure occupied the entire sitting to the exclusion of the Midwives Bill. The situation thus created seemed practically hopeless from the point of view of the

Members interested in the further progress of the measure They put it down on several occasions after Government business, but it never was reached at an hour when the rules of the House enabled it to be discussed as an opposed measure Convinced apparently that nothing more could be done in the House of Commons the promoters had a similar measure introduced in the House of Lords on the afternoon of Friday, March 9th, by Lord Glenesk But within about two hours of this second introduction the Bill in the House of Commons had actually been read a second time and referred to a Committee. This unexpected achievement was brought about by a strange combination of circumstances In the House of Commons the usual business at this period of the session on Fridays, is Committee of Supply, but on this particular Friday, owing to the Navy Estimates having been practically finished at the previous sitting and the absence of Mr Wyndham through illness making it impossible to proceed with the Army Estimates, the Government decided to devote the sitting to the advancement of certain of their legislative proposals Mr. Balfour set out in the orders of the day a list of four Government Bills, the most important being the second reading of the Factories and Workshops Bill Had this list been taken as it stood it would have occupied the entire sitting, but to meet the wishes of certain members Mr. Balfour agreed to withdraw from it the Factories and Workshops Bill. The programme of business thus attenuated was got through soon after half past five o'clock, and Mr Goschen acting for the Government at once moved the adjournment of the House. He did so on the ground that the House had met for Government business and this being over they should proceed no further As it chanced there were three Bills promoted by private Members on the order paper and the friends of one of these, the Sale of Intoxicating Liquors to Children (No 2) Bill, claimed that they should be taken The Government resisted the claim for a time, but eventually gave way, with the result that not only this Bill but the one that came after it, the Midwives Bill, were discussed and advanced The proceedings were conducted in a very small House and in the absence of many Members interested in the Midwives Bill Very few of the medical members were present. Just one further word of explanation before we give our report of what was said and that is that the whole proceedings on the Bill, which included two divisions, occupied only a little more than three-quarters of an hour.

Mr Heywood Johnstone moved the second reading He explained in a few sentences the main provisions of the Bill which, of course, are familiar to our readers He also explained that he and the other promoters of the Bill had been aided by the General Medical Council in its preparation. In justifying legislation of this description he recalled to the House the action of continental nations and the need there exists in this country for thoroughly trained midwives The general effect of the Bill, he said, would be that without some satisfactory proof of training and capacity a woman would not be allowed to practise at all as a midwife, and when she had given this proof and began to practise she would be subjected to the control of a supervising body He asked the House to consider the suffering of the poor women of England from the treatment of rough, ignorant, and in many cases dissolute women, of whose former career nothing perhaps might be known, and to give the Bill a second reading leaving defects, if it had defects, to be rectified in committee

Mr Schwann seconded the motion He dealt particularly with the attitude of the medical profession towards the Bill, saying that while at one time legislation of this kind had been opposed by the medical profession there were now unmistakable signs that the attitude of a great number of medical men had changed

Mr. T P O'Connor said he was opposed to the Bill and should fight it as vehemently, vigorously, and persistently as he could and he believed he should receive the support of many Members if not the majority of the House His conviction was that the result of this measure would be to aggravate the evils which it was designed to put down. Going on to refer to the assistance poor women often receive from friendly neighbours the hon Member was interrupted by

Mr Heywood Johnstone, who said he knew two cases this winter in his own small village of friendly neighbour's assistance which had the most sad results

Mr. O'Connor said that sad results there might be in these cases, but if this Bill passed sad results would be multiplied by 10 The midwife would assume all the duties and responsibilities, not merely of a nurse, but of a fully qualified medical practitioner Here was surely a case where if ignorance was bad half knowledge was worse—that half knowledge which assumed the appearance and privileges of whole knowledge He felt confident that if this Bill were passed and these women were registered they would not hesitate to undertake cases themselves, and if they did so there would be grave risk of serious results Not only so, but he charged the Bill in its results as being calculated to increase malpractice by giving these women the right to claim to interfere in cases of confinement, and in that way to cover under the cloak of confinement what was really an illegal practice. He denied that the majority of the medical profession was in favour of the Bill On this point he had received a letter from the Editors of The Lancet, the highest and most influential authority in the medical profession This letter stated that a circular lett had been sent amongst the members of the medical profession in England, and up to the date of writing the Editors of The Lancet had received 7250 replies According to the promoters of this Bill they ought all to have been replies in favour of the Bill, but such was far from being the case An analysis of the replies showed that 1547 medical men were in favour of the Bill, 640 were indifferent, while the remaining 5000 odd were opposed to it. He would remind the House that while a medical man went through five years training' before he could enter on the work of his profession and take charge of midwifery cases under this Bill midwives were only to have three months' training

Mr Heywood Johnstone said there was nothing about three months' training in the Bill The proposed Midwives Board would lay down its rules for the training of midwives, these rules being subject to the approval of the General Medical Council.

Mr O Connor said he could not regard the proposed arrangement as safe or satisfactory. He made no complaint against the promoters of the Bill for bringing it forward on the present occasion though he confessed he was not prepared for it He submitted that it was a measure so serious and so opposed by skilled medical opinion that it demanded a great deal better consideration than could be given to it at this time, and therefore he moved the adjournment of the debate

Mr Robert Ambrose seconded this motion.

On a division the motion was rejected by 127 to 56 votes

The debate accordingly proceeded.

Mr Vicary Gibbs said that anyone listening to the speech of Mr T P O'Connor would suppose that all the great medical authorities were against this measure He simply wished to say that the General Medical Council, the Royal College of Physicians, and the Royal College of Surgeons were all in favour of it

Dr Tanner, who had given notice of a motion for the rejection of the Bill, said he opposed it as a medical man conscious of the injury it was likely to cause to women of the humbler classes. The leading medical paper in this country was The Lancet and The Lancet had taken a plebiscite upon the question, and this showed that an overwhelming majority of the medical profession was against the Bill. This fact was surely enough to make Parliament pause before taking this important step in legislation For himself he regarded it as a retrograde step, one calculated to undo existing statutes designed for the benefit of suffering humanity.

Mr Hazell, speaking amid cries of "Divide," which made him practically inaudible, supported the Bill

Mr Robert Ambrose then proposed to speak, but the Speaker ruled that as he had seconded the motion for the adjournment he had already taken part in the debate

The motion for the second reading of the Bill was carried by 124 to 34 votes A full list of the names of members who voted respectively for and against the motion for the second reading will be found at page 798

Mr Heywood Johnstone moved that the Bill be referred to the Standing Committee on Law

Dr Tanner asked whether a number of medical members would be added to this committee for the consideration of this particular measure

The Speaker said that was a matter for the Committee of Selection to whom applications could be made

The motion, being put to the House, was adopted without division

The consequence of this reference to the Standing Committee is that the Bill avoids the Committee Stage in the House and comes back merely for Report and Third Reading

Appointments.

Successful applicants for Vacancies Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to The Lancet *Office, directed to the Sub-Editor, not later than 9 o clock on the Thursday morning of each week, for publication in the next number.*

Allport, R H, L.R C P Lond, M R C S, has been appointed Assistant Medical Officer for the Renfrew road Workhouse of the Parish of St Mary, Lambeth London, vice J C Harcourt, resigned.

Balck, J A, M B, Ch.B Edin., has been appointed House Physician, Royal Hants County Hospital, Winchester

Belding D T, L.R C P Lond., M R.C S, has been re-appointed Medical Officer of Health by the East Dereham Urban District Council

Bennett, W Edward, F R.C S Eng, has been appointed a Demonstrator of Anatomy to the Queen's Faculty of Medicine, Mason University College, Birmingham, vice W P Haslam.

Blair, Charles S, M.D Durh., F R C S Eng, has been appointed Assistant Surgeon to the Western Ophthalmic Hospital, London.

Blakiston, Arthur Alexander, M R C S, L.S A., has been re-appointed Medical Officer of Health for Glastonbury.

Briscoe, William Thomas, A.B., M.D., M.Ch. Dub., has been re-appointed Medical Officer of Health for Chippenham.

Brook, Charles, M.R.C.S., L.S.A., has been appointed Consulting Surgeon to the Lincoln County Hospital.

Brook, W. H. B., M.D., B.S. Lond., F.R.C.S., has been appointed Surgeon to the Lincoln County Hospital, vice Charles Brook.

Browne, George, has been appointed Dispensary Medical Officer of Ballynahinch, vice J. Dickson, resigned.

Brown, W. Langdon, M.A., M.B., B.C. Cantab., M.R.C.P., has been appointed Assistant Physician and Pathologist to the Metropolitan Hospital, Kingsland-road, N.E.

Burrell, L. C., M.B., B.C. Camb., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Kew Sanitary District by the Richmond (Surrey) Board of Guardians.

Burton, H., L.R.C.P. Irel., M.R.C.S., has been re-appointed Medical Officer of Health by the Marple District Council.

Cadell, N. P., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health by the Frimley Urban District Council.

Campbell, E. Kenneth, M.B., F.R.C.S., has been appointed Surgeon to the Western Ophthalmic Hospital, London.

Clarke, H. A., M.D., M.Ch. Irel., has been appointed Visiting Physician to the City Hospital, East, Liverpool.

Coates, W. H., M.A., M.B. Durh., L.R.C.P. Lond., M.R.C.S., has been re-appointed Medical Officer by the Partrington Rural District Council.

Coombs, M. L., L.R.C.P., L.R.C.S., has been re-appointed Medical Officer of Health by the Newport Town Council, Isle of Wight.

Craven, R., M.B., C.M. Edin., has been appointed Medical Officer for the Chipping District of the Clitheroe Union.

Donagan, A. E., B.A., L.D.S., has been appointed Lecturer on Dental Mechanics in Mason University College, Birmingham.

Emerson, T. G., M.D., M.Ch. Irel., has been re-appointed Medical Officer of Health by the Wantage Urban District Council.

Evans, J. Jameson, M.B., C.M., F.R.C.S. Eng., has been appointed a Demonstrator of Anatomy in Mason University College, Birmingham.

Felce, Stamford G., M.D., B.C. Cantab., has been appointed Medical Officer to the Willesden Parish Infirmary.

Gaylor, E., L.R.C.P. Edin., L.F.P.S. Glasg., has been re-appointed Medical Officer of Health by the Alfreton Urban Council.

Giles, A. E., M.D., M.R.C.P. Lond., F.R.C.S. Edin., has been appointed Honorary Gynæcologist to Out-patients, Tottenham Hospital.

Gilmer, H. A. H., M.B., Ch.B. Edin., has been appointed Assistant House Surgeon to the Northern Hospital, Liverpool.

Grace, Gerald, L.R.C.P. Lond., M.R.C.S., L.S.A., of Chipping Sodbury, has been appointed Civil Surgeon to No. 10 General Hospital, South Africa.

Green, E. T., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory Acts for the County Borough of Birkenhead, Wallasey Urban District Council, and the Townships of Bidston-cum-Ford and Noctorum, in Wirral Rural District.

Hays, A. G., L.R.C.P., L.R.C.S. Edin., F.F.P.S. Glasg., has been appointed Medical Officer for the Third Sanitary District of the Brackley Union, vice H. R. Jacobs, resigned.

Hemsted, Henry, Jun., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Royal Hants County Hospital, Winchester.

Herbert, B. H., M.R.C.S., has been re-appointed Medical Officer of Health by the Uttoxeter District Council.

Hollings, C. E., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer of Health by the Driffield Rural District Council.

Holt, H. M., M.R.C.S., D.P.H. Edin., has been re-appointed Medical Officer of Health by the Malton Urban District Council.

Hutchinson, J. A., M.D. Durh., M.R.C.S., has been re-appointed Medical Officer by the Northallerton Rural District Council.

Inverarity, James M., L.R.C.P., L.R.C.S. Edin., has been appointed Civil Surgeon to the 4th Battalion Scottish Rifles, now *en route* for South Africa.

Jones, William Watkin, M.D., C.M. Edin., D.P.H. Cantab., has been appointed, *pro tem.*, Medical Officer of Health by the Merthyr Tydvil Urban District Council.

Legate, R. L., L.R.C.P., L.R.C.S. Edin., has been re-appointed Medical Officer by the Christchurch District Council.

Leslie, R. Murray, M.B. Edin., M.R.C.P. Lond., has been appointed Senior Medical Registrar and Medical Tutor, King's College Hospital, London.

Leslie, R. Murray, M.A., M.D., M.R.C.P. Lond., has been appointed Honorary Physician to In-patients, Tottenham Hospital.

Lloyd, W. H., M.R.C.S., has been re-appointed Medical Officer of Health by the Llandilo Urban District Council.

Macdonald, J. H., M.B., B.Ch. Glasg., has been appointed Assistant Medical Officer (Pathologist) at the Glasgow District Asylum, Woodilee, Lenzie.

Mackay, J. Y., M.D. Glasg., has been appointed to the Principalship of the University College, Dundee.

Mordaunt, L. J. Pavillet, M.R.C.S., L.R.C.P. Lond., has been appointed Junior House Surgeon to the Miller Hospital, Greenwich-road, S.E.

Parsons, J. Frederick, M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health for Frome, Somerset.

Pim, J. H., L.R.C.P., L.R.C.S. Irel., has been appointed Medical Officer and Public Vaccinator for the Billinghay Sanitary District of the Sleaford Union.

Richards, H. M., M.D. Lond., B.S., L.R.C.P., M.R.C.S., has been appointed Medical Officer of Health for the Borough of Croydon.

Rorie, George A., M.B., Ch.B., has been appointed Senior Assistant Medical Officer at Cumberland and Westmorland Asylum, vice J. W. Leitch, resigned.

Rowlands, W. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Workhouse of the Bromsgrove Union, vice C. Kidd, resigned.

Seacome, A. F., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Assistant Medical Officer at the Workhouse of the Township of Toxteth Park, Liverpool.

Seddon, Albin J., L.R.C.P. & S. Edin., L.F.P.S. Glasg., D.P.H. Edin., has been appointed Medical Officer for the Frome District by the Frome Board of Guardians.

Smith, Edmund Moody, M.D., C.M. Edin., D.P.H. Cantab., has been appointed Medical Officer of Health for the City of York, vice *Robert Cattley, resigned.*

Steele, Herbert, L.R.C.P. Lond., M.R.C.S., of St. Marychurch, Torquay, has been granted a commission as Surgeon-Captain in the Eighth Division, and is proceeding to South Africa.

Thompson, George W., M.B., C.M. Edin., has been appointed Assistant Surgeon to the Western Ophthalmic Hospital, London.

Weaver, J. J., M.R.C.S., has been appointed Medical Officer of Health for the Borough of Southport.

Williams, H., M.D. St. And., L.R.C.P. Edin., M.R.C.S., has been re-appointed Medical Officer of Health by the Richmond, Yorks, District Council.

Wright, William, M.B., B.Ch., M.R.C.S., L.R.C.P., has been appointed Lecturer on Osteology and Senior Demonstrator of Anatomy in Mason University College, Birmingham.

Vacancies.

For further Information regarding each vacancy reference should be made to the advertisement (see Index).

Birkenhead Borough Hospital.—Visiting House Surgeon. Salary £75 a year, with board, lodging, and washing (no wine, spirits, or beer). Additional fees allowed for reporting certain infectious diseases, &c.

Birmingham and Midland Ear and Throat Hospital, *Edmund-street*, Birmingham.—House Surgeon. Tenable to Oct. 31st next. Salary at the rate of £60 per annum, with board, lodging, and washing.

Bradford Royal Infirmary.—House Surgeon, for twelve months, unmarried. Salary £110 per annum, with board and residence.

Bury Infirmary.—Junior House Surgeon. Salary £80 per annum, with board, residence, and attendance.

Cardiff Infirmary.—Assistant House Physician for six months. Salary at the rate of £50 per annum, with board, washing, and apartments. Also Resident Medical Officer for three years. Salary £100 per annum, with board, washing, and furnished apartments.

Cumberland and Westmorland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer, unmarried. Salary £100 a year, with board and residence.

Devon County Asylum, Exminster, *Devon.—Third Assistant* Medical Officer. Salary £120, rising to £150, with board, lodgings, &c.

Down (County) District Asylum, Downpatrick.—Assistant Medical Officer, unmarried. Salary £100 per annum, with furnished apartments, board, washing, and attendance.

Dumfries and Galloway Royal Infirmary.—House Surgeon. Salary £50 per annum, with board and washing. Also Assistant House Surgeon. Board and washing provided.

East Sussex County Council.—Consulting Medical Officer for one year. Honorarium 100 guineas, and travelling expenses.

Hamlet of Mile-end Old Town, London.—Assistant Resident Medical Officer at the Workhouse Infirmary, Bancroft-road, Mile-end, E. Also as Assistant Medical Officer for the Workhouse and School, unmarried. Salary, an inclusive one of £120, with board, lodging, and laundry and an allowance in lieu of beer. Applications to the Clerk to the Guardians, Bancroft-road, Mile-end, E.

Harris Parish Council, for the Southern Division of Harris.—Medical Officer. Salary £90. Apply to Mr. Thomas Wilson, Solicitor, *Lochmaddy, Clerk.*

Hospital for Consumption and Diseases of the Chest, Brompton.—Assistant Physician. Also Resident House Physicians for six months. Honorarium £25.

Hospital for Sick Children, Great Ormond-street, Bloomsbury, London.—House Physician for six months, unmarried. Salary £20, with board and residence in the hospital.

Hospital for Women, Soho-square (The London School of Gynæcology).—Clinical Assistantships.

Kent and Canterbury Hospital, Canterbury.—Assistant House Surgeon, unmarried. Salary £60 a year, with board and lodging.

Lincoln County Hospital, *Lincoln*.—Assistant House Surgeon for six months. Honorarium £10 for that period, with board, residence, and washing.

Lincoln Hospital for the Insane.—Assistant Medical Officer. Salary £100.

N.B —A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents.

THE CHURCH MILITANT FOR SANITATION IN HURDSFIELD

Hurdsfield is a suburb of Macclesfield with a population of 4000, and Macclesfield, as everyone knows, is a large town with a population of 39 000, in Cheshire famous for its silk manufacture This being so it is astonishing to find (from statements which have appeared in the local press—statements made at public meetings and elsewhere) that the arrangements for the disposal of sewage in Hurdsfield are on a par with those which obtained in London in the eighteenth century The state of matters stands as follows Macclesfield is asking for powers to borrow nearly £7000 for street improvements None of this sum, however, is to be spent in Hurdsfield Ratepayers of, and others interested in, Hurdsfield have therefore in a public meeting demanded that Hurdsfield shall be included in the scheme, even if more money has to be spent The reasons for this request were set out with exceeding plainness in a letter signed "Wm Laycock, Chairman of the said meeting and of the said School Committee Wm Laycock is, to his credit be it said, the Reverend William Laycock, Vicar of Hurdsfield and the letter in question was published in the local papers and also sent to the Local Government Board It states that—1 The main sewer of the whole borough comes through Lower Hurdsfield and Garden street 2 In Hurdsfield there are about 900 houses of these 370 are unsewered 3 Garden street contains 70 houses and has all the sewage of the borough passing through it It has three sewers, three sets of gas mains, and two water mains passing through it, and yet all its houses except seven are unsewered 4 Steeple street, with 28 houses, is unsewered and unpaved 5 Hurdsfield road containing with its small side streets 230 houses is totally unsewered Road gutters do not communicate with any drains but are fitted with dummy traps and grids From Higher Hurdsfield without the borough, flows a drain which so far as is known, carries all the sewage from Hurdsfield road, from the canal to the church, into the Bollin In part of its course it is uncovered and at times is most offensive 6. Lansdowne-street contains 30 houses and a large school and is totally unsewered and unpaved It has old soughs or drains which empty themselves into a pool This sewage, mixed with other water passes through the boilers of certain mills afterwards into the Bollin 7 The ashpit system is in vogue and the contents are apparently emptied into the street and then removed This occurred in the case of a house where there was a patient suffering from enteric fever The street is neither paved nor macadamised

At the monthly meeting of the Macclesfield Town Council held on Feb 7th the Chairman of the Highways Committee felt obliged to say something about the contents of this letter He contended that Mr Laycock's assertions were not well founded As to Garden street and Steeple-street the committee had estimates prepared for the work but they had been handicapped by the absence of a steam roller He had it from the medical officer conclusively that the very part of the town which Mr Laycock spoke of was one of the most healthy parts of the borough He did not think it should go forth that Hurdsfield was neglected Councillor Hood said that the Vicar was only asking for his rights and that he would back him out, tooth and nail Councillor Isherwood said that Eastgate required attention as soon as possible

A public meeting of the inhabitants of Hurdsfield was held on Feb 19th, at the Daybrook street School, "to ratify and confirm whatever has already been done by the Vicar and others in connexion with the unsewered and unpaved streets in Hurdsfield Mr T C Horsfall J P , was in the chair, and among others were present the Vicar and Councillors Hood and Isherwood The latter in the course of the proceedings mentioned that the last report of the medical officer of health was an argument in favour of the Highways Committee Eventually however the meeting unanimously passed the following motion — "That this public meeting of the ratepayers *and inhabitants of Hurdsfield heartily approves of* and confirms what has been done concerning neglected Hurdsfield by the Vicar and others and hereby states that his letter to the Local Government Board was no exaggeration of facts but a true statement of the present condition " We have always maintained, and we are glad to see that Mr Horsfall also maintained in his speech, that the clergy should be in the forefront in all efforts to improve the physical condition of the people There seems to be no doubt whatever that Mr Laycock's statements are the simple truth Hurdsfield is apparently in the dangerous condition not of having no drainage but of having bad and inefficient drainage at least so we gather from the mention of the "soughs whilst reference to the steam roller is not pertinent. Nobody either lays drains, connects houses with drains, or empties ashpits by means of a steam roller We do not gather so far that the Highways Committee have come to any conclusion, but we earnestly hope that the Local Government Board will make a strict inquiry into all the circumstances Meanwhile we offer our congratulations to the Vicar for giving voice to the complaint of his people

TROUSSEAU'S WINE.

To the Editors of THE LANCET.

SIRS,—In the annotation headed "Valvular Disease in Old Age" in THE LANCET of Feb. 3rd, 1900, you mention the use of Trousseau's wine as very beneficial in that disease. Will you or any of your readers kindly inform me, through your esteemed journal, the exact formula and the process of making the diuretic wine? May I also ask you to state the formula and process of making the German speciality called "urocidine"? I am, Sirs, yours faithfully,

Parel, Bombay, India, Feb. 24th, 1900. A SUBSCRIBER.

*** Uricedin is composed of citrate of potash, sulphate of soda, chloride of sodium, and citrate of lithium. We do not fancy that the exact formula has been published. Trousseau's wine was similar to the preparation mentioned in the annotation, but we have not the exact formula at hand. Possibly some of our readers can supply it.—ED. L.

"LAURIA FUND."

To the Editors of THE LANCET.

SIRS,—The above fund is now closed and we enclose herewith a final statement of subscriptions, the total being £115 16*s.* 6*d.* A cheque has been handed to Mrs. Lauria for this amount.

We are, Sirs, yours faithfully,
JOHN H. BARRS.
EDWARD B. HARTNELL.

6, Wandsworth Bridge-road, S.W., *March 12th*, 1900.

THE SANITARY BANDELET.

WE have received from Mr. Louis Nelicker, of 29, Bedford-road, Rockferry, Cheshire, a sample of his patented sanitary bandelet for ladies' use. It has the ordinary form and appearance of articles for this purpose, being a thin pad or cushion about eight inches long and three inches wide, with loops at each end for attachment to a waistbelt. The bandelet is filled, not with wadding, wood-wool, or other fibrous material, but with a fine soft inorganic powder, for which great absorptive properties are claimed.

WANTED A HOME.

To the Editors of THE LANCET.

SIRS,—Could you or any of your readers tell me of any home where an elderly lady can be cared for? She is the widow of a medical man, and was formerly a nurse; she is now over 70 years of age and almost destitute. I am, Sirs, yours faithfully,

March 12th, 1900. MEMBER.

WANTED A REMEDY.

To the Editors of THE LANCET.

SIRS,—A woman is very much troubled by the growth of two patches of long hairs, one on either side of her chin. I shall feel extremely obliged if any of your readers will kindly suggest some simple but efficacious means of getting rid of them. She objects to electrolysis.

I am, Sirs, yours faithfully,

March 14th, 1900. L.R.C.P.

THE SEXUAL QUACK.

THAT noisome person, the sexual quack, is tolerably well known upon this side of the Atlantic. His literature is invariably of the same type—false pathology mixed up with lies about "loss of vitality" and other imaginary symptoms, with an undercurrent of semi-"religious" remarks about what the Creator has intended. We have recently received from a correspondent in India a pamphlet issued by the North American Specialists Company, who live at 194, Broadway, New York, and the object of this company appears to be to induce the weak-minded to buy the American Wafers. From page 8 of the pamphlet we learn that "from the glacial regions of Iceland to the arid sands of Patagonia and from the point where the sun exhibits his rising beams to the occident where he glows in brilliant setting, no remedy or combination of remedies exist which has gained the phenomenal success which has crowned the American Wafers." This is, in Thackeray's words, "a hoighth of foine writing," but its astronomical views are peculiar. The wafers are of four kinds, and Nos. 1, 2, and 3 are prepared in two strengths. Accompanying the pamphlet is a confidential consultation sheet which the sufferer is supposed to fill up together with his name and address. We have pointed out before how writing to abortion quacks opens the door to blackmail and we can say the same about filling up such papers as are now before us, although, of course, there is no criminality in question. But if anyone were idiotic enough to fill up the questions which are on the consultation sheet things might easily be made very unpleasant for him. The correspondent who sends us the pamphlet informs us that it was sent to an officer of his regiment and also that such literature is being sent broadcast over India at the present day. The amount of filth circulated by means of the post-office is incalculable and it is quite time that some means should be taken of putting a stop to the practice.

AN EIGHTEENTH-CENTURY MEDICAL BILL.

A LEGAL correspondent has been kind enough to forward the enclo bill which he came across in the exercise of his profession. It bill for medicines and dressings supplied in 1776 to a Mrs. Ell Hadderton but does not apparently include charges for professio attendance. It runs at follows:—

1776. March 24th. Mrs. Ellen Hadderton

Debtor to S. Jeffery.

	s.	*d.*
To three purging potions	2	0
To a cooling collyrium	1	3
Ditto repeat	1	3
Two Blystering plasters ... ... And Dressings for Ditto	1	6
£0	6	0

Receiv'd Ap. 27th, 1776,
The above in full, S. Jeffery.

Mrs. Hadderton, it will be seen, was very prompt in her payme and, allowing for the difference in the value of money, the pr seem to be about the same as in the present day.

AN "AUTOMATIC DRY SEAT" FOR TRAMWAYS, &c.

MR. J. JACKSON of Black Swan Works, Ripon, sends to us ticulars of an "automatic dry seat," which should supply a pressing want of those who travel on tramways and omnibuses. framework of the chair is very similar to the seats with move backs so common on tramcars, but attached to the back of the cha few inches above the seat is a strip of canvas which extends over seat and under the front edge, where it is affixed to an oscillating controlled by a strong spring. The seat when not in use is always kept covered. Before a passenger sits down he has merely move the back of the chair, when the canvas covering is dr automatically below the seat. The movement can be easily rever at the end of the journey by the conductor.

◆

Aliquis.—There is an unwritten rule that when in a puerperal case attendance is prolonged beyond the normal period the practition entitled to charge additional fees according to the number of his v and the demands upon his time. The practitioner himself, from own knowledge of the case and the circumstances, ought to be best judge of the additional fees which he should charge. The detailed is not one in which we should advise the unwritten rule t pushed very far.

W. W. B. (Edinburgh).—The gist of the letter is published in columns. Our correspondent must excuse us from replying to privately. With all the will in the world time does not permi to do this.

Mr. W. P. Phillips.—We have no information on the subject. It w be better for the young woman to communicate with the matron the large general hospitals.

Dubitans.—We do not think the cockade should be worn.

H. A.—We do not recommend practitioners to the public.

COMMUNICATIONS not noticed in our present issue will receive atten in our next.

METEOROLOGICAL READINGS.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. II. of 1899, which was completed with the issue of Dec. 30th, and the Title-page to the Volume, were given in THE LANCET of Jan. 6th.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1899 are now ready. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 15 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

Communications, Letters, &c., have been received from—

A.—Señor M. D. Adame, Seville; Messrs. Allen and Hanburys, Lond.; Messrs. Ayrton and Saunders, Liverpool; *Abstainers'* and General Insurance Co., Birmingham; Mr. W. F. Abbott, Addlestone; A. W. W. D.; Aylesbury Dairy Co., Lond.

B.—Sir W. Banks, Liverpool; Mr. D. F. Bolton, Usk; Burton-on Trent Infirmary, Secretary of; Messrs. J. Beal and Son, Brighton; B. F. D.; Messrs. The Goulstonian Lectures

ON

THE TYPHOID BACILLUS AND TYPHOID FEVER.

Delivered before the Royal College of Physicians of London

BY P. HORTON-SMITH, M A, M D CANTAB, F R C P LOND,

ASSISTANT PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND TO THE METROPOLITAN HOSPITAL ASSISTANT MEDICAL TUTOR TO ST BARTHOLOMEW'S HOSPITAL

LECTURE I[1]

Delivered on March 20th

MR PRESIDENT AND GENTLEMEN,—In the Goulstonian Lectures which he delivered nearly half a century ago the late Sir William Jenner expressed in appropriate language the feelings which should guide the lecturer in the choice of his subject "It is fitting," he said, "that on this occasion the junior Fellow of the College should treat only of matters concerning which he has reason to hope his knowledge is inferior to that of his hearers in a less degree than on any other" In taking typhoid fever for my subject I trust that I may be fulfilling these conditions I propose to discuss the pathology of the disease from its bacteriological aspect, for it is in this direction that recent researches have most materially extended our knowledge To day I desire, after considering some important points in connexion with the typhoid bacillus itself, to discuss the relationship which the latter bears to an ordinary case of typhoid fever

Sir William Jenner[2] in his classical paper, published just 50 years ago showed that in their clinical symptoms and in their morbid anatomy typhoid fever and typhus fever were separate diseases A few months later, in a paper read before the Royal Medical and Chirurgical Society,[3] he supported his former thesis by proving, so far as inductive reasoning could prove the point, that the specific causes of the diseases were distinct What the nature of the cause might be he did not discuss Indeed, the words which Dr. Peter Mere Latham[4] had written some years before still fairly well expressed the difficulty felt by even the very ablest minds in forming any definite conception of the pathology of the infectious diseases Speaking of the epidemic prevalent at the General Penitentiary in 1825 and speculating on its cause Dr Latham was obliged to confess that "the present state of our knowledge does not enable us to ascertain what the essence of the disease was, and indeed the search after the essence of any disease beyond the point at which it begins to fall within the reach of the senses has seldom brought the pathologist to any more certain conclusion than this—namely, that it consists in a morbid disposition or action which is *sui generis*" In truth, no further advance was possible until Pasteur had opened up a new world for us by demonstrating the connexion of micro-organisms with disease

As soon as this had been effected numerous observers turned their attention to typhoid fever, each eager to discover the micro organism in question This honour was, however, reserved for Eberth[5] of Zürich who in 1880 succeeded in demonstrating in sections the presence of the true typhoid bacillus in the spleen and mesenteric glands After its discovery and when its cultural characteristics had been pointed out by Gaffky,[6] it seemed an easy matter to identify the microbe, one or two cultures alone being sufficient to make certain of its identity In 1885, however, the bacillus coli communis was discovered by Escherich[7] and it rapidly became evident that much greater care would have to be exercised in isolating the real typhoid bacillus Indeed so great became the difficulty in distinguishing the typhoid bacillus from some varieties of bacillus coli that in 1890 Rodet and Roux, representing the Lyons school of bacteriology, firmly maintained the view that distinction between them was impossible, that is to say, that by no morphological, cultural or other tests was it possible to certainly distinguish the typhoid bacillus from members of the coli group, and, in fact, that the typhoid bacillus was nothing more than bacillus coli endowed temporarily with the power of producing a specially virulent toxine and thereby causing the disease This we now know to be incorrect It is, without doubt, true that the typhoid bacillus is a member of the great coli family It is, in fact, nothing more than the member of that family which by a process of evolution has acquired the most highly specialised properties at the expense of some of the more common qualities possessed by the humbler members of the group, but the view that the ordinary bacillus coli communis can be converted at any moment into the typhoid bacillus, or that the reverse can obtain, is not supported by any evidence whatever. The species, though having a common ancestor, are now absolutely distinct But though this is so, and though with care the typhoid bacillus can be accurately distinguished from the other members of the group, it is by no means a simple matter, and I propose to dwell for a short time on the methods which should be employed for making the diagnosis, more especially as no definite criteria have as yet been agreed upon by bacteriologists, and consequently much valuable work has been vitiated by insufficient testing of the isolated micro-organisms

THE IDENTIFICATION OF THE TYPHOID BACILLUS

In the first place it may be said that there is not the smallest difficulty in distinguishing the typhoid bacillus from what may be called the classical bacillus coli communis They resemble each other superficially, but differ essentially in that the typhoid bacillus does not, for example, form gas bubbles in dextrose gelatin, does not clot milk, nor form indol The two can therefore be readily distinguished The difficulty, however, in diagnosing the typhoid bacillus arises from the fact that the classical or typical bacillus coli communis is by no means the sole representative of this great group Indeed, we now have to recognise the fact that the term "bacillus coli" does not refer to a single bacillus but to a great group of microbes some of which are identical with the classical bacillus coli while others very closely indeed resemble the typhoid bacillus Innumerable intermediate forms also exist The credit of first thoroughly bringing home this important point belongs to Dr M H Gordon[8] of St Bartholomew's Hospital who, in an admirable paper published in 1897, very clearly demonstrated its truth Dr Gordon obtained from various sources, such as stools, urine, sewage, milk, water, &c, over 100 micro organisms which resembled the bacillus coli communis morphologically and in its growth on gelatin and agar He then proceeded to investigate the attributes of each, for example, their power of producing gas and indol, their capacity for acidifying and coagulating milk, the number of their flagella, &c In this way he was able to demonstrate clearly what had been foreshadowed by Lawes and Andrewes,[9] that the 100 or more microbes, apparently all similar, could really be divided into as many as 16 different and stable varieties, according as they had lost one or more of the properties characteristic of the typical bacillus coli communis Large as the number may seem, it by no means includes all the varieties known, indeed, to it we must now add several which resemble the typhoid bacillus most closely—for example, Petruchsky's bacillus fæcalis alkaligenes, Gärtner's bacillus enteritidis, Nocard's bacillus psittacosis Günther's bacillus der fleischvergiftung, Basenau's bacillus morbificans bovis (sometimes grouped together as "the Gärtner group"), and many others, such as for example Houston's bacillus typhosus simulans isolated from Thames mud These micro organisms are important in themselves and they derive additional interest from the fact that they are not isolated bacilli but are merely representatives of a large group, continually being added to, from which the typhoid bacillus has to be very carefully distinguished

In making, then, the diagnosis between the typhoid bacillus and its allies, on what tests should we rely? It may be stated at once that since no test is absolutely specific, with the exception of the one introduced by Pfeiffer, which in England at least is not always easy to perform, reliance must be placed on a series of tests. Let us now consider the most important of these and how they should be applied.

Morphology and motility.—In the first place, it should be noticed that an examination of the micro-organisms under the microscope often gives valuable indications provided that a fresh gelatin culture be used (agar cultures being much less distinctive) and that the examination be made in a drop of broth. Under these circumstances the greater length of the typhoid bacilli, their greater motility, and especially the curious serpentine movement of the longer forms, should at once suggest this micro-organism. Unfortunately, however, it cannot do more, for Gärtner's bacillus, Günther's bacillus, and Nocard's bacillus psittacosis, unlike the commoner varieties of the coli group, *exactly* resemble the typhoid bacillus in these respects. Still, the tests are of value in suggesting the presence of the typhoid bacillus and in excluding many of the commoner varieties of bacillus coli.

Recently, however, it has been shown that bacilli exactly resembling each other in appearance, size, and motility may yet differ radically in the shape and number of their flagella, and the point is of some importance in the diagnosis of the typhoid bacillus. Thus the flagella of this micro-organism are long and wavy and from eight to 12 in number on each bacillus, while those of the ordinary bacillus coli are shorter and vary in number from one to three. Until quite recently, therefore, it was thought that here bacteriologists possessed an infallible means of differentiating the two micro-organisms. But this is not so, for though the majority of the members of the coli group have but from one to three flagella, there are others which possess more, while one or two of the higher members of the group are multi-flagellated in exactly the same way as is the typhoid bacillus. These variations in the number of the flagella possessed by members of the coli family are well shown in the accompanying reproductions of photographs, for which I am indebted to the kindness of Dr. Gordon. We see from them that while very often it is possible to distinguish the typhoid bacillus from its allies by the flagella test, yet sometimes this fails. Thus bacillus enteritidis, and probably also Nocard's bacillus, exactly resemble the typhoid bacillus, in this respect. As a rule, however, even in the multi flagellated forms, slight differences can be made out and the test, therefore, is of very considerable importance. Thus the bacillus represented in photograph 1 was a variety of bacillus coli, which formed no gas, did not clot milk, and formed no indol, but the number and arrangement of its flagella at once enabled it to be distinguished from the typhoid bacillus. In all cases of doubt, therefore, the flagella should certainly be stained.

Cultivation tests.—I do not propose to say anything about the growths of this great group of microbes on surface gelatin or agar, for the shades of differences noticed are too fine to be of any value as differential tests. Nor need I delay over the potato culture, hallowed though it be by tradition, owing to the fact that it was introduced by Gaffky himself, who first succeeded in cultivating the bacillus. The invisible growth, however, which may occur in the case of the typhoid bacillus if the reaction of the potato be suitable is not uncommonly also obtained with other members of the coli group, especially the higher members, and the test therefore becomes of but little use. So, too, with Elsner's medium, at first so much vaunted. According to my experience many varieties of bacillus coli grow on it exactly like the typhoid bacillus, and the medium, difficult at any time to prepare, becomes therefore of but little value.

Dextrose-agar and dextrose-gelatin.—Extremely important, however, as differential tests are the dextrose agar and dextrose-gelatin shake cultures; probably, indeed, of all the culture tests they are the most important. Their value depends on the fact, first pointed out in 1890 by Theobald Smith,[10] that typhoid bacilli, grown in a medium containing 2 per cent. of dextrose, never decompose the latter with the formation of gas bubbles, while numerous members of the coli group do. Gordon, working with dextrose-gelatin, found that of his 16 varieties 11 produced the phenomenon, while the remaining five did not. Experience, however, shows that, contrary to the former tests, the chief members of the Gärtner group, otherwise closely allied to the typhoid bacillus, are sharply differentiated by this test. Thus of the four examples which I have been able to examine all gave a positive result. Petruchsky's bacillus fæcalis alkaligenes, however, is an exception; like the typhoid bacillus it forms no gas bubbles. As a rule, too, gas bubbles, if they are going to appear, generally are seen within 24 or 48 hours; occasionally, however, in dextrose-gelatin at least, they are delayed, it may be as long as for 10 days. If this medium be used it is well, therefore, to keep the tubes for a month before deciding that the reaction is really negative—the tests, then, are of the highest value, for though by no means conclusive in themselves, they yet often effect a distinction exactly in the cases where it is most required.

Litmus milk.—Another very important test is the litmus milk test. Originally introduced in 1891 by Chantemesse and Widal,[11] it was perfected in the following year by Dunbar,[12] who pointed out the importance of noticing the change of reaction as well as the presence or absence of coagulation. Grown in this medium and incubated at 37° C. the typhoid bacillus rapidly produces a slight acidity in the milk, but never, even after some months, does it coagulate the latter. With the typical bacillus coli communis, however, the reverse obtains, for the milk is clotted in from 24 to 48 hours, while the amount of acidity formed is greatly in excess of that ever produced by the typhoid bacillus. What, now, are the limitations of the test? 1. First, as regards the coagulation of the milk. Here, again, as with so many other tests, it is by no means infallible. Gordon found that 10 out of his 16 varieties of bacillus coli clotted while the other six failed to do so; moreover, of the four highly specialised members of the group which, I have examined each had lost this power and so by this test could not be distinguished from the typhoid bacillus. A point of great importance to be borne in mind in conducting the test is that the coagulation of the milk in these cases is not uncommonly long delayed. As a rule it occurs within the first four days, but it is by no means rare with the less common varieties of bacillus coli to find it occurring first in the second, the third, or even the fourth week after inoculation of the tube. The lesson, therefore, to be drawn from this fact is that every tube should be observed for at least a month before stating that the result is negative. 2. Secondly, with regard to the production of acidity. This, I believe, is subject to less variation than the power of clotting milk, that is to say, that most varieties of bacillus coli form acid rapidly and form it more abundantly than does the typhoid bacillus. But, unfortunately, the test fails when we come to the more highly differentiated forms, for the Gärtner group all produce approximately the same amount of acid in milk as does the typhoid bacillus. So far I have spoken of the acidity, noticed up to the end of a week, the time usually allowed by observers before the tube is cast aside. If, however, the tubes be kept for a month before being discarded, as I have suggested, further important changes in the reaction may often be observed. Thus even at the end of this period the reaction of a typhoid milk culture is still nearly always acid. Such, at least, has been the case in the great majority of the different typhoid bacilli, over 20 in number, which I have examined. Occasionally, however, the reaction has been faintly alkaline. Supposing, however, we take the cultivations not of the typhoid bacillus but of the other highly specialised members of the coli group, bacillus enteritidis and its allies, we find that in certain of them, Gärtner's bacillus itself for example, at the end of a month the reaction is highly alkaline and has acquired a curious but very definite slaty blue colour. Without going so far as to affirm that a typhoid bacillus could never give rise to such a change of reaction we may say at least that it can only rarely occur, and we should do well, therefore, to regard all such bacilli with grave suspicion until their identity with the typhoid bacillus has been otherwise most fully proved. We, may, then, affirm that the litmus milk test is of considerable value as a means of distinguishing the typhoid bacillus from the varieties of bacillus coli, if performed in the manner suggested, that is to say, if the culture is kept at 37° C. for at least one month. If discarded at the end of a week, as is the usual procedure, valuable indications are often lost.

Indol test.—Another test commonly applied to distinguish the typhoid bacillus is the indol test, introduced by Kitasato[13] in 1889. The bacilli are grown in broth at 37° C.,

Photographs showing the Variations in Flagella Possessed by Different Members of the Coli Family
(Prepared by Van Ermengem's Method)

Fig 1

Fig 2

and the cultures are tested at the end of a variable time, generally one week, to see whether indol is present in them or not. Typhoid bacilli under these conditions never form indol, various members of the coli group do. If the test is to be of any real value, however, it must not be performed before the end of one month, for in many cases the formation of the indol is much delayed. Even, however, if we take a month as the standard the test not uncommonly fails, and it should be noticed that this failure is especially common among the higher members of the group. Thus no indol was produced by any of the four members of the Gärtner group which I have examined, and the test, therefore, as a means of diagnosis becomes of infinitely less importance than the dextrose-agar or dextrose-gelatin test or the litmus milk test.

Media of Capaldi and Proskauer.—We now come to two tests for the typhoid bacillus which are too little known. I refer to the media introduced by Capaldi and Proskauer.[14] Into their composition I need not enter; suffice it to say that in Medium I. the bacillus coli grows readily and forms strong acidity, while the typhoid bacillus will not grow at all; in Medium II., on the contrary, while both grow readily the typhoid bacillus alone forms acid. The tests, like all the others which we have been discussing, have their limitations; but that they are of considerable value is shown by the fact that by means of them two of the four members of the Gärtner group which I have examined, as well as Houston's four bacilli (bacillus typhosus simulans, *a*, *b*, *c*, and *d*), were at once differentiated from the typhoid bacillus. In these media, then, we have a valuable auxiliary means of distinguishing the typhoid bacillus from the other members of the coli group, rendered more important by the fact that the reaction is quickly given (in from 24 to 48 hours) and that the media can be easily prepared.[15]

Serum test.—We may now pass to the serum test, the most important of the tests which are commonly employed for the identification of the typhoid bacillus. This test, however, like all the others, only becomes of real diagnostic value if applied in the proper way. A not uncommon method of procedure is to take a broth culture of the suspected bacillus and to add to it sufficient serum from a patient suffering from typhoid fever to make a dilution of 1 in 20. Should clumping occur within an hour, or it may be two or even three hours, the bacillus is said to be the typhoid bacillus. Such a method of procedure, however, is really of no value, for we now know that in very many cases the serum of the typhoid fever patient is not a simple serum containing only the typhoid agglutinins but is a complex body containing the agglutinins of other microbes as well, and often those which we are most anxious to distinguish from the typhoid bacillus. Moreover, even if a simple typhoid serum is used—that is to say, a serum obtained from an animal immunised artificially by injections of typhoid culture, a fallacy may come in. Thus it is well known—it was, indeed, pointed out by Durham[16] in his earliest communication on the subject—that these sera are not "specific" but rather "specialised." The result is that if a very strongly agglutinating typhoid serum is used and a dilution of merely 1 in 20 be employed a bacillus, allied to the typhoid bacillus, but *not* the typhoid bacillus, may be clumped. Thus it was shown that Gärtner's bacillus may be agglutinated under these conditions, and other microbes of a similar kind also exist.

How, then, should the test be applied so as to guard against the possibility of such errors? In the first place, where possible a simple typhoid serum should be used for the test, that is to say one obtained from an animal highly immunised against the typhoid bacillus. Where, however, as is commonly the case, this is impossible, and a serum from a typhoid patient has to be employed, it should be one which agglutinates strongly, at least in dilutions of 1 in 1000, and the following method of procedure should be used. The serum should be tested against the standard typhoid bacillus (agar cultures in all cases being used) and the highest dilution in which a complete reaction is obtained in one hour should be worked out. When this is done then the unknown bacillus must be tested in like manner so that the maximum agglutinating power of the serum towards it may be also determined. If then the two prove equally sensitive towards the serum, each giving a complete reaction in one hour to a similar high dilution, then it may be said for certain, *provided it has answered the other tests*, that the unknown bacillus is also the typhoid bacillus; for experience shows that though a typhoid serum may agglutinate other microbes, for example, Gärtner's bacillus, as well as the typhoid bacillus, yet it probably never clumps the former in dilutions over 1 in 500 (Durham)[17] and indeed very rarely reaches such a height. If, then, the serum test, applied in this way, has given a positive reaction and the morphological and cultural tests are also affirmative, then we may be certain that the bacillus is also the typhoid bacillus.

Variations in clumping power according to the culture used; necessity of using cultures on solid media in testing typhoid bacilli.—Is, however, the converse true? Are we justified in saying that a bacillus which is only slightly sensitive to a strong typhoid serum is therefore not the typhoid bacillus, even though in all other respects it may resemble the latter? In other words, are all typhoid bacilli agglutinated by a given serum to an exactly equal extent? The majority of observers, Widal,[18] Bensaud,[19] Durham,[20] and others, have not noticed marked differences in this respect, and they believe, therefore, that typhoid bacilli from every source are agglutinated approximately to the same degree. Van de Velde,[21] however, from his observations on 20 different typhoid stocks found very considerable variations in the clumping power. The following observations are of interest in this connexion, for they show that using 18-hour broth cultures, as is now the usual practice, undoubtedly marked variations in the clumping power of different typhoid bacilli do exist. In these experiments typhoid sera of different typhoid clumping power were tested against the laboratory standard typhoid bacillus and also against typhoid bacilli isolated from stools, urine, mesenteric glands, and spleen—bacilli which, be it remembered, were found to resemble the typhoid bacillus in all respects both morphologically and culturally. As a result it was found that their clumping powers were by no means similar. Thus in Experiment 1 and Experiment 2 the bacilli isolated from the stools and urine of the same patient were agglutinated to a somewhat higher degree than was the standard bacillus. In Experiment 3, on the other hand, the bacilli which had been obtained in pure culture from the spleen and mesenteric gland of a patient who died from typhoid fever on the twenty-first day were found to clump in a far less degree than the standard bacillus, while in Experiment 4 the bacillus, which had been isolated in pure culture from the spleen of a fatal case of typhoid fever was found to have no clumping power at all in a 1 in 20 dilution, though tested both against the highly agglutinating blood of a patient inoculated against typhoid fever and also against the milk of a patient who had recently had typhoid fever and in whom this secretion was strongly agglutinating. Experiment 5, also, is interesting. In this case two standard typhoid bacilli, both of which, that is to say, had been used in the routine work of the laboratory and which were very sensitive to typhoid serum, were tested against a feebly agglutinating serum, and the difference in their agglutinable power was distinct. The one clumped fairly in a 1 in 100 dilution, the other only in a dilution of 1 in 20. (See Table I.)

There can be no doubt, then, that if broth cultures be used typhoid bacilli often differ markedly among themselves in the ease with which they are affected by the typhoid agglutinins. But is this difference constant and have we here evidence of "varieties" of typhoid bacilli? It would seem not, for if we use cultures on solid media (agar and gelatin) this variability seems much less marked. This was especially noticeable in the case of the bacillus in Experiment 4, which, though it reacted like typhoid to all the morphological and culture tests enumerated above and had been obtained in pure culture from the spleen in an early fatal case, yet neither was agglutinated by typhoid serum when tested by Dr. Andrewes, nor by the typhoid milk when tested by myself. Feeling certain, however, that the bacillus *was* the typhoid bacillus I tried once more, but on this occasion used an agar culture (18 hours), testing it against a second sample of milk obtained from *the same* patient as before. A very different result was now obtained. After mixing the culture and the milk agglutination immediately became apparent in a dilution of 1 in 20, and in a few minutes was complete, while in a dilution of 1 in 500 a complete reaction was obtained within the hour—a result exactly similar to that given by the standard typhoid bacillus when tested against the sample of milk now under consideration.

This same extraordinary difference in sensibility to agglutination between broth and agar cultures I have noticed in the case of five other typhoid bacilli, isolated from different patients (and in a seventh case a similar result was obtained on using a gelatin culture), so that probably it is not really very uncommon. It is possible, too, that it should be associated with a fact observed by Kraus.[22] This experimenter showed that if broth cultures of the typhoid bacilli be incubated for some days and be then filtered the filtrate gave rise on the addition of typhoid serum to a precipitate closely resembling in appearance that produced by agglutinated micro-organisms. The reaction was *specific* and only occurred when typhoid serum was added. It may be that the constituent of the bacillary body on which the agglutinins act, and which thus seems normally to pass into the surrounding liquid, may in some cases diffuse much more easily, and even after 24 hours be no longer present in the bacilli themselves. We should thus have an easy explanation of the absence of the reaction in the broth grown bacilli and its presence in those obtained from solid media. Be this as it may, the obvious moral to be drawn from the fact is that in testing the agglutinable qualities of a suspected bacillus cultures on solid media should always be used, and especially therefore agar cultures.

So far, too, though my experiments are not numerous enough for me to speak with certainty, I have not noticed more than slight differences between different typhoid bacilli, provided agar cultures be compared. The experiments of Dr. Klein,[23] however, showing that under abnormal conditions the agglutinable property of the cholera vibrio can be lost, should warn us not to be too dogmatic on this point in the case of the typhoid bacillus. Indeed, the matter requires further investigation.

Pfeiffer's test.—Should, however, a bacillus be discovered which culturally or morphologically resembles the typhoid bacillus in all respects and which yet agglutinates but feebly or not at all, then one further test must be applied to it—namely, Pfeiffer's test. This consists in injecting into the peritoneum of a guinea-pig a 10 times fatal dose of the bacillus in question, together with a very small quantity (0·001 cubic centimetre may be quite sufficient) of typhoid serum from a highly immunised animal. If the bacillus in question be the typhoid bacillus, then while a control animal injected *only* with the bacillus will die this animal will recover, the bacilli being converted first into granular masses (Pfeiffer's phenomenon) and then gradually disappearing under the influence of the lysogenic properties of the serum. Such a serum, however, is *specific*, and can therefore only protect in minute doses, against the corresponding micro-organism. If, therefore, the bacillus in question be not the typhoid bacillus, but some variety of bacillus coli, the animal will infallibly die just like the control animal. This test is of the highest importance, for if properly performed a positive result is infallible. It is unfortunate, therefore, that the test, owing to the difficulties connected with it, cannot be made of more general application. It should, however, always be applied in any case in which there can be doubt as to the nature of the micro-organism. If, for example, a bacillus which should fail to agglutinate nevertheless should react like the typhoid bacillus to this test, then we must accept it as the latter.

Such, then, are the most important methods which we possess for the identification of the typhoid bacillus. Without doubt by far the most important of these are the last two, the agglutination test carried out in high dilutions and Pfeiffer's test, but the others cannot be neglected. Indeed, in view of the extreme importance of the subject it would be well if before pronouncing any bacillus to be the typhoid bacillus, more especially if it be found in some unusual situation, whether within or without the body, the micro-organism were subjected as a minimum in all cases to the following tests which for convenience I here recapitulate: (1) morphology and motility (as observed on gelatin), (2) flagella; (3) gelatin and agar slope culture, (4) dextrose agar or gelatin shake cultures, preferably the former, (5) litmus milk (one month), (6) broth culture (no indol—one

[23] Report of the Medical Officer of the Local Government Board, 1896-1897.

month); (7) Proskauer and Capaldi medium 1 (no growth 48 hours); (8) Proskauer and Capaldi medium 2 (growth and acidity 48 hours); (9) agglutination test (high dilutions—1 in 1000 at least—agar cultures); and (10) in cases of doubt Pfeiffer's test.

These tests are long and tedious, but it must be borne in mind that we know very few of the saprophytes with which we are surrounded and that at any moment one may be discovered having greater affinities with the typhoid bacillus than those already described. Remembering, too, the history of our subject it behoves us to use exceptional care, for only in this way can we hope that our results may withstand the just criticism of future observers.

THE TYPHOID BACILLUS AS A SAPROPHYTE.

The life-history of the typhoid bacillus may be divided into two great chapters—the one dealing with the bacillus in its relation to the human body, the other describing its existence after leaving the shelter of the organism. It is to the former of these that I propose chiefly to confine myself, for our knowledge of the latter phase of the life-history of the micro-organism is as yet most limited. We are ignorant indeed whether under the conditions found in nature the bacillus can ever multiply and increase in numbers, or whether after a longer or shorter duration it gradually dies out.

The former view was recently brought forward by the late Sir Richard Thorne Thorne from a consideration of the fact that it was otherwise very difficult to explain the endemic character of typhoid fever in certain towns and districts. At the present time, however, the view is unsubstantiated by bacteriological evidence. It is true that, as Dr. Sidney Martin[24] has shown, the typhoid bacillus can multiply if implanted in organically contaminated soil previously sterilised, but whether it would also multiply were the soil unsterilised and were it therefore exposed to the inevitable struggle for existence has not yet been shown. Indeed, the work of Lawes and Andrewes who showed that the typhoid bacillus rapidly died out if planted in sewage, whether sterilised or not, would rather suggest the improbability of its doing so.

Again, in support of the active saprophytic growth of the typhoid bacillus the very careful observations of Lösener[25] have been cited. In 1895 this observer, using all the means of differentiation then at his command, was able to find bacilli quite indistinguishable from the typhoid bacillus in very various situations, for instance, in the intestines of a pig, the water of his laboratory, and in a specimen of uncontaminated soil. Unfortunately, however, neither the serum nor Pfeiffer's test were then available, so that we are not justified in concluding that the bacilli in question really were the typhoid bacilli. On the contrary, the extraordinary difficulty experienced in finding the latter in water obviously specifically polluted would suggest that they were not.

We must allow, then, that so far there is no proof that the typhoid bacilli can multiply outside the human body. Our increasing knowledge of typhoid fever, too, enables us to explain satisfactorily many outbreaks of the disease without such an assumption. Thus it is fully established that a person may, though apparently restored to health, remain infectious for months and years after an attack of the fever—a fact in itself sufficient to account for many outbreaks of the disease. If, too, we remember that the bacillus has great power of resisting the effect of desiccation, remaining alive, it may be, for over a year in the dried condition (Schiller),[26] it becomes easy to understand how bacilli eliminated from the body may later pass into the atmosphere in the form of dust and cause disease at long periods after every fresh source of infection has been really removed. These facts should, in many cases at least, render unnecessary a belief in the actual growth of the bacillus outside the human body. The question, however, is one which the future alone can finally settle.

THE TOXINES OF THE TYPHOID BACILLUS.

The pathology and symptoms of any infectious diseases are intimately bound up with poisons elaborated by the micro-organism in question. This subject was recently brought before the College by Dr. Sidney Martin in his Croonian Lectures, and I will not now do more than draw attention to two points in connexion with the toxines formed by the typhoid bacillus. The first point to note is that the poison is for the most part intracellular. It is contained in the bodies of the bacilli themselves and during their life passes only to a comparatively slight extent into the surrounding medium. Funck,[27] indeed, came to the conclusion that this never occurred, and this though he used both ordinary bacilli and also those whose virulence had been considerably heightened by successive passages through the guinea-pig. In both cases he found that if broth cultures were made and incubated at 37° C. for at least a month and then filtered through a Chamberland's bougie, the filtrate was innocuous. This, too, was my own experience, using a typhoid bacillus recently isolated and possessing moderate pathogenic power. Thus in the case of a rabbit whose initial weight was 1360 grammes I injected intravenously, in three successive doses, 18½ cubic centimetres of a filtered broth culture, the latter having been previously incubated at 37° C. for 42 days. This was followed 10 days later by a single subcutaneous injection of 18 cubic centimetres of the same filtered culture. A we
later the animal was killed, four weeks from the init
injection. During the injections it had appeared in perfe
health, its temperature had remained normal, and at
death it had gained 231 grammes. Post mortem, beyo
slight parenchymatous changes in the liver and kidn
nothing abnormal was observed. The poisonous characte
of the filtered culture were therefore in this case almost *ni*

There is no doubt, however, that in some cases the toxin
do diffuse somewhat into the surrounding liquid. Thus I
Sidney Martin[28] was able on several occasions to produ
lowered temperature, diarrhœa, and eventually death, by t
injection of small doses (three cubic centimetres) of the filter
culture. But although this is so, and though there can be
doubt that sometimes to a slight extent the toxines do pa
into the culture media, it remains true that the poisons a
for the most part intracellular—a fact at once proved
noticing the incomparably greater effect produced on t
animal by the injection of cultures in which the bacilli ha
been killed, but their bodies have been allowed to rema
in the liquid. It may be accepted, then, that the toxines
the typhoid bacillus are for the most part contained with
the bacillus itself and are chiefly set free when the latter
destroyed. The fact is of interest from a clinical point
view, for it shows that even when the body has acquired
a case of typhoid fever sufficient bacteriolytic power
destroy the bacilli we ought not to expect, in the absence
antitoxin formation, of which as yet there is no evidenc
an immediate fall of temperature. The first effect, indee
of the destruction of the bacilli would be a further outflo
of poison into the general circulation, and only as this
gradually excreted should we expect the temperature to fal
In this way an explanation offers itself of the fall by lys
which is so characteristic of the disease.

The second point which it is of interest to note is that t
toxine is a very feeble one as compared with those of certai
other micro-organisms. Thus, in order to kill a guinea-pi
of 300 grammes weight Sanarelli[29] had to use a subcutaneo
injection of 4 5 cubic centimetres of his toxine, whi
in the case of tetanus Vaillard was able to obtain a sol
tion $\frac{1}{10000000}$ cubic centimetre of which was able to ki
a guinea-pig. In the case of diphtheria, too, the dos
necessary may be extremely small. It is obvious, then, tha
to explain the symptoms of typhoid fever the number
bacilli present in the body should be very large, so tha
sufficient toxine may be formed. As we shall see, this
what does occur. So far from being limited to one situatio
as in tetanus, the bacilli find their habitat in many orga
and in diverse situations of the body and are present
enormous numbers.

EXPERIMENTAL TYPHOID FEVER.

Before a given micro-organism can be accepted as th
cause of a disease two points must be clearly established
In the first place the organism must be constantly present i
the tissues of patients suffering from the disease, an
secondly, the bacillus, having been obtained in pure cultur
and grown artificially through several generations, must b
able to reproduce the disease.

With regard to typhoid fever there can be no doubt abou
the former of the two premisses. The bacillus is present i
the body in all cases of the disease. Indeed, this is so wel
recognised abroad that puncture of the spleen with th
object of isolating the bacillus is one of the recognise

means of clinical diagnosis practised by the continental physician. Is, however, the second premiss true. Can the bacillus when reintroduced again give rise to the disease? For a long time this was doubted, innumerable attempts to reproduce the disease in animals, both by feeding and by inoculation, having resulted in failure. Animals, in fact, as a rule are not susceptible to typhoid fever such as it occurs in man. The observations of Mr. Bland Sutton,[30] however, on the animals (lemurs, monkeys, beavers, &c.) in the Zoological Gardens seemed to show that, under certain conditions at least, the lower animals could suffer from true typhoid fever. At all events, the clinical symptoms in these animals, fever, in some cases of six weeks' duration, and diarrhœa, the ulceration of the Peyer's patches and solitary follicles found post mortem, and the mode of death, brought about in one case at least by general peritonitis and in another by sudden hæmorrhage from the bowel, gave a picture quite indistinguishable from the disease occurring in man. Moreover, this disease was raging in the neighbourhood at the time. It was reasonable, therefore, to hope that further persistent effort might eventually result in producing by means of the typhoid bacillus typical typhoid fever, and it would seem that Remlinger has lately succeeded where so many others have failed. His experiments, it should be noticed, were carried on during the summer in Tunis, and it is conceivable that the tropical climate may by its effect on the animals have had something to do with the successful result. Remlinger[31] experimented first on rabbits. His method consisted in feeding them on vegetables previously soaked in water largely diluted with typhoid cultures. Under this treatment and after a short incubation period three of the eight rabbits used became ill. The temperature rose gradually and remained raised; the animals were affected with diarrhœa and they refused food and rapidly lost weight. The temperature charts strongly resembled in appearance those of typhoid fever, the temperature remaining up for from 12 to 16 days. In two cases death followed and in one recovery. In all three cases Widal's reaction, 1 in 50, was obtained from the blood during life. In the two cases which died the post-mortem appearances obtained were those of typhoid fever. The ileum was found to be much injected, the Peyer's patches were swollen and hypertrophied, and near the cæcum there was some ulceration The mesenteric glands were swollen, the spleen was enlarged, and in one case diffluent. In both cases typhoid bacilli were isolated from the latter organ With white rats, also, a very similar result was obtained. It would seem, then, that there cannot be any further doubt that typhoid fever can be communicated to animals by means of the typhoid bacillus. The last link, therefore, in the chain of evidence proving the causal connexion of the bacillus with the disease may be regarded as complete.

HUMAN TYPHOID FEVER; THE DISTRIBUTION OF THE BACILLUS IN THE BODY.

I may now pass from the disease experimentally induced in animals to typhoid fever as it occurs in man, and I propose first of all to discuss the relationship which the bacillus bears to an ordinary case of the disease. This may be best effected by considering in such a case what are the situations of the body in which the bacillus may be found.

Mesenteric glands and spleen.—Eberth,[32] the discoverer of the bacillus, was able to demonstrate its presence microscopically in the mesenteric glands and in the spleen. He did not, indeed, find the bacillus in all cases, but he was successful six times in the spleen and 12 times in the mesenteric glands out of 23 cases which he examined. Further investigation, however, not only confirmed his discovery but showed that the presence of the micro-organisms in these situations was constant. In rare cases, it is true, a culture from either organ may remain sterile, but this doubtless arises from the curious manner in which the bacilli are scattered in little masses through the tissue so that occasionally the inoculating needle fails to come in contact with them.

Peyer's patches.—With regard also to the Peyer's patches themselves and the solitary follicles of the intestine there is no doubt that, if examined early enough, typhoid bacilli may be demonstrated therein.

The liver.—Another organ in which the typhoid bacillus is constantly present is the liver. Thus Gaffky found it here in 12 out of his 13 examinations, and his results have been fully confirmed. In the liver again, just as in the Peyer's patches, the mesenteric glands, and the spleen, the typhoid bacilli are found aggregated together into their little characteristic masses. It might at first seem somewhat surprising that the liver should contain the typhoid bacillus, but it is not difficult to explain. As we shall see, the bacilli must in all cases at some period of the disease pass into the blood and hence be first carried to the liver. Now this organ, as Lemaire[33] has clearly shown, undoubtedly plays a very active part in eliminating the typhoid bacillus from the circulation, even more so than the spleen. For both reasons, therefore, it is easy to understand how the liver comes to be a constant habitat of the bacillus in typhoid fever.

The bile.—This, however, has been known for long. Much more recent is the knowledge that the bile in the gall-bladder in the majority of cases contains the bacillus, very often in pure culture. For this advance in our knowledge we are especially indebted to Chiari[34] who in 1893 examined the bile in 22 cases of typhoid fever, and in 19 of them found the typhoid bacillus therein. Moreover, in 15 of these it was present in pure culture. Somewhat similar results had, indeed, been obtained before experimentally. Thus Blachstein and Welch[35] in 1891 showed that if mild doses of typhoid culture were injected intravenously into rabbits, on examination after death the bile would often present a pure culture of the typhoid bacillus. To Chiari, however, belongs the credit of demonstrating the fact in cases of typhoid fever in man and his observations have been fully confirmed. Thus in 10 cases at St. Bartholomew's Hospital in which the bile was examined, in nine of them was the bacillus found; in each case also it was in pure culture. Flexner[36] was, however, less fortunate, finding them only in seven out of 14 examinations. It should be noticed, also, that in very many cases the micro-organisms are present in great numbers, so that if a drop of bile be examined under a microscope numerous bacilli may be seen.

The bone marrow.—Another situation, also, in which the bacilli have been recently demonstrated with great frequency is the bone marrow. This was shown as recently as 1894 by Quincke.[37] He examined the marrow of the ribs in nine cases and in eight of them he found the typhoid bacillus in considerable numbers. In seven the bacilli were present in pure culture. His method of diagnosing the bacilli, it is true, left much to be desired; still there is no doubt from the confirmation which his observations have received that the bacilli found by him were really true typhoid bacilli. At St. Bartholomew's Hospital the bone marrow has been examined in six cases and in four of them a pure culture of typhoid bacilli was obtained. In the other two cases typhoid bacilli were not found, but only bacillus proteus vulgaris and bacillus coli.

The kidney.—We may now pass to another organ which contains sometimes the specific micro-organism—namely, the kidney. As a matter of fact, however, in contradistinction to what we have seen to be true for the liver, the spleen, and the mesenteric glands, the bacillus is by no means constantly found here. Its presence, indeed, is exceptional. Thus, to mention only recent observations, Flexner[35] found it here in one case out of four, in addition to two cases of obvious typhoid septicæmia in which the bacilli were found in the blood and all the organs after death. Wright and Stokes[39] found it in three cases out of seven. For myself I may say that I have examined the kidneys bacteriologically on eight occasions. Twice only were the typhoid bacilli found, and in both of these the micro-organism was present in large quantities also in the blood. In the remaining cases the kidneys were sterile three times, and on three occasions they contained bacillus coli communis, twice in pure culture and once combined with bacillus proteus vulgaris. We shall probably, therefore, be not far wrong if we conclude that it is the exception rather than the rule for typhoid bacilli to be found in the kidney after death, though in rare cases, as I shall show, it may become localised here and give rise to an acute nephritis. Although, however, this is so, it is probable that during life it is by no means uncommon for typhoid bacilli to be carried every now and then in small numbers to the kidney and then to be rapidly excreted into the urine, for how else are we to explain the frequent occurrence of the bacilli in this excretion?

[39] Boston Medical [illegible] Jo[illegible] [illegible], p. 33[illegible]

The lung.—In other organs, too, the typhoid bacillus has been described not infrequently, for example, in the lung. Here the bacillus does undoubtedly occur, but not, I believe, as frequently as is sometimes imagined. Thus, in five cases in which I have examined the lung, in one only has the typhoid bacillus been present, this being a case of thrombosis of the pulmonary artery and infarction of the lung. In four others (two examples of lobar pneumonia, one of hypostatic pneumonia, and one of simple congestion), the typhoid bacilli were not found, though in two cases the bacillus coli was present in considerable numbers. The late Professor Kanthack also had a similar experience, since in four cases of broncho-pneumonia he was never once able to discover the specific organisms, though bacillus coli was present on more than one occasion.

In less suspected regions, too, as, for example, the testicle, the typhoid bacillus may be present even in the absence of any definite complication.

It will be seen, then, from what has been said that the bacilli are found in uncomplicated cases of typhoid fever with great constancy in the Peyer's patches, in the solitary follicles, in the mesenteric glands, in the spleen, and with great frequency in the red marrow of the bones and in the bile, not uncommonly in the kidney, and sometimes in the lung. In other organs, too, such, for example, as the testicle, their presence has been discovered. The relative frequency of their occurrence in these situations is shown in the following table from the St. Bartholomew's Hospital post-mortem records, the observations having been made by the late Professor Kanthack, by Dr. Andrewes, and by myself.

TABLE II.—*Showing the Relative Frequency of Occurrence of the Typhoid Bacillus in the Various Organs of the Body.*

—	Number of times examined.	Typhoid bacilli found.
Spleen	21	20
Mesenteric gland	13	12
Liver	4	3
Bile	10	9
Bone marrow	6	4
Kidney	8	2
Blood from the heart	10	2
Lung	9	1
Thyroid	1	0

It is evident, from a consideration of this table, that the bacilli are always widely distributed in the body and there would seem to be only one means by which such a wide distribution could be effected, and that is through the blood. Are, however, the bacilli found in the blood?

THE BLOOD.

In answering this question it will be well to consider first of all the results which have been obtained from an examination of the blood in fatal cases. In such cases, though it is not by any means the rule to find the typhoid bacillus in the blood after death, yet it occurs there by no means infrequently. Thus Vincent[40] found the bacillus in one case out of four and Flexner[41] in two cases out of six. Klein[42] recorded their presence in two out of four cases, a similar result also being obtained by Wright and Stokes. Lately I have examined the blood after death on nine occasions, and three other cases are recorded in our records at St. Bartholomew's Hospital. Of these 12 cases two gave a positive result, the typhoid bacilli being demonstrated in the blood with ease. Of the remaining 10 cases, five were sterile, three contained bacillus coli and bacillus proteus vulgaris, and two the pyogenic cocci. Table III. shows these results more exactly.

TABLE III.—*Showing the results of Post-mortem Examination of the Blood in Fatal Cases of Typhoid Fever.*

Total number of cases examined, 12.

Sterile	5	Streptococci, and staphylococci	1
Typhoid bacilli	2	Bacillus coli	2
Streptococci	1	Bacillus coli and proteus	1

It is interesting to note in passing that one of the cases in which the typhoid bacilli were found in the blood was that of a girl who died on the fourteenth day from the "severity of the disease" and "heart failure." It is possible that not a few of the cases which die thus early may really prove to be cases of similar marked typhoid septicæmia.

It will be seen, then, that out of a total of 30 cases in which the blood was examined after death the typhoid bacillus was found in nine of them. Evidently, then, in *fatal* cases it is not uncommon for the typhoid bacilli to be present in the blood in considerable numbers. But does the same occur in *non-fatal* cases during life, and is it easy to demonstrate the presence of the bacilli in the circulating blood? It may be said at once that it is a matter of extreme difficulty; indeed, it was held until quite recently to be almost impossible. Seitz[43] failed in seven cases, Janowski[44] in 27, Lucatello[45] in nine, Klein[46] in 10, and Fraenkel and Simmonds[47] in six. Occasionally, however a positive result has been recorded; thus Thiemich[48] was once successful out of seven cases, Wiltschur (quoted by Janowski) once in 31, and Ettlinger twice out of 10 cases. Lastly, Stern[49] recently reports two successes and Block[50] one. In all seven successful cases are here mentioned against 110 failures. As a matter of fact, however, these results are misleading, for Kühnau[51] has lately shown that if much larger quantities of blood be taken than was used by the earlier observers—five to ten cubic centimetres, for example—and especially if the blood be immediately diluted after it has been obtained, to diminish its bactericidal power, then it is possible to obtain the bacillus from the blood during life in a very considerable percentage of cases. Working on these lines Kühnau was successful in 11 out of 41 cases. It should be noticed, however, that the number of colonies which developed were always extremely small, the total number varying from two to nine. If, then, when we examine only 10 cubic centimetres of blood we are able to demonstrate the bacillus in 25 per cent. of cases of typhoid fever, it is no rash assumption to believe that, were we able to examine the whole, we should always find it in the circulating blood during life. The reason why the bacilli are not found in greater numbers in the blood during life probably depends on the fact that in ordinary cases the blood is an extremely bad medium for their growth. Indeed, owing to its bactericidal power it is likely that such bacilli as do not succeed in finding shelter in some viscus are rapidly destroyed. This would not occur to the same extent in fatal cases (perforation and similar cases being excluded), for often it is owing to such patients acquiring this power that a fatal termination ensues, and on this fact doubtless in part depends the greater ease with which the bacilli can be demonstrated in the blood after death. We may believe, therefore, as indeed we should expect from the distribution of the bacillus in the body, that the micro-organisms pass into the blood in all cases of typhoid fever. They are, however, rapidly eliminated from it into the various organs or destroyed. In rarer cases, on the contrary, probably always fatal, when the blood fails to acquire bactericidal properties, the typhoid bacilli may develop therein and be found after death in considerable numbers.

THE TYPHOID ERUPTION.

The general distribution of the typhoid bacillus in the organs of a patient suffering from typhoid fever has now been considered, and it is obvious from the facts brought forward that typhoid fever is far from being merely an intestinal disease. Bearing this in mind it will be interesting to consider the relation of the bacilli to the "spots"—the roseolous eruption characteristic of the illness.

The early observers for the most part were unable to demonstrate the presence of the bacilli in this lesion. Thus Wiltschur,[52] Seitz,[53] Curschmann,[54] Merkel and Goldschmidt,[55] and others in their numerous experiments all obtained negative results, while Rutimeyer[56] obtained one positive result in six observations In the light of these results the statement of Neuhaus,[57] made as long ago as 1886, that he had obtained nine positive results in 15 cases, was generally received with incredulity It may be said, therefore, that until quite recently the received opinion was that the spots in typhoid fever were not due to a local growth of the typhoid bacilli, but were more probably due to the absorption of the typhoid toxines into the general circulation

Observers, however, were not entirely satisfied and continued working at the subject In 1895 Thiemich[58] reported that he had found the bacilli in the spots in three cases out of seven, while early in 1899 appeared the important paper by Neufeld,[59] which apparently explained the discrepancies between the results of various observers Neufeld argued that if the bacilli really were the cause, it was evident they were only able to obtain their foothold in the skin and subcutaneous tissue for a very short time, otherwise the spots themselves would not be so fleeting—hence to find them *spots should be examined quite early in their development.* Secondly, to eliminate as far as possible the bactericidal power of the blood itself, which would come in contact with the bacilli as soon as the spot was opened, he advocated the use of liquid culture media (broth) in order to dilute the blood and so diminish this source of error The value of these suggestions was shown by his results He examined the spots in 14 cases and in 13 he obtained a positive result His methods of testing the bacilli obtained were, it may be stated, admirable These results were confirmed in November of last year by Curschmann[60] of Leipzig Following Neufeld's methods he examined the spots in 20 cases and in 14 he was able to demonstrate the typhoid bacilli, certain of his negative results also being evidently due to his having in some cases chosen spots already beginning to fade Lastly, within the last few weeks, Richardson[61] of Boston, an extremely careful observer, reports similar successful results, the bacilli being isolated from the spots on an average six days *before* the Widal reaction was obtained It should be added, however, that the number of typhoid bacilli in each individual spot must be very small, for though many observers have endeavoured to demonstrate them microscopically therein, they have never yet succeeded (Ernst[62] and Neufeld[63]) There would seem, then, to be hardly any doubt whatever that the rose spots are truly specific in nature and are the result of the direct presence of the typhoid bacillus

THE EXCRETIONS

Having now discussed the usual distribution of the specific microbe in the various organs in an uncomplicated case of typhoid fever we may turn our attention to the excretions, for it is of great importance to know how far each of these is infectious There are four which have been so described with more or less frequency—the sweat, the expectoration, the fæces, and the urine

The sweat —With regard first of all to the sweat There would seem to be *a priori* no reason why typhoid bacilli should not be found therein, since there is no doubt that the bacillus always passes into the blood At present, however there is really no evidence to show that they do occur in this excretion Three positive observations have, it is true, been recorded in addition to numerous negative ones, but the observers, Geisler[64] and Sudakoff,[65] seem to have taken no special care to prove the identity of the micro-organism found, and for the present, therefore, their results may be disregarded

The expectoration —With regard to the expectoration the case is somewhat different I have shown that the typhoid bacillus may be present in the lung in large numbers and whenever this occurs we must believe that the sputum will always contain the micro-organism Fortunately, however, these cases are rare, but nevertheless we should always look upon the expectoration in a case of typhoid fever, if there be any, as a possible means of spreading the disease and should take measures accordingly

The fæces —The idea that the fæces were the chief means whereby the disease was conveyed seems to have been first explicitly stated by Canstatt in 1847, and in this country Dr William Budd long and ably maintained this view.[66] Indeed, it is probably due to his enthusiastic teaching that the doctrine of the intensely contagious character of typhoid stools throughout the whole course of the disease has held its ground ever since Lately, however, a distinction has been drawn between the alvine dejections and the urine, and though it is absolutely certain that excremental pollution in its broad sense is the great cause of the spread of typhoid fever, it is at the present moment still debated how great is the share taken by the fæces and the urine respectively, and at what period of the disease each should be regarded as most dangerous In the early days of bacteriology no difficulty was experienced in isolating the typhoid bacilli from the stools It was open to anyone to effect this The rapid progress of knowledge, however, soon showed that these were not typhoid bacilli, but merely bacillus coli communis or one of its numerous varieties, and it was then recognised that so far from being easy it was a matter of most extraordinary difficulty to find the true bacilli in the fæces Thus Walthelet[67] in 1895 could only isolate the micro organism in four stools, though he examined as many as 51 In 1896, however, the introduction of Elsner's medium somewhat facilitated matters and led at all events to renewed investigations As a result we may say that there can be now no reasonable doubt that in the first and second weeks of typhoid fever the stools are highly infectious The numerous

* + signifies a positive result typhoid bacilli being found in the stools — signifies a negative result, typhoid bacilli not being found T N = Temperature normal.

For further details consult THE LANCET *May 20th, 1899, p 13*[illegible] observations of Pollak,[68] Jemma,[69] and Richardson[70] show that the typhoid bacilli can be found in them in practically every case at this period of the disease. An extremely important point, it may be remarked in passing, for it completely annihilates the fanciful but well-known theory of Sanarelli that typhoid fever is primarily a septicæmia and that the intestinal lesions are merely secondary. At later periods of the disease, however, and also during convalescence, if care be taken to obtain fæces uncontaminated with urine, it is extremely difficult to isolate the micro-organism. Thus Jemma,[71] Richardson,[72] and Lazarus[73] all found great difficulty at this stage, and my own observations bear out their results. Thus out of 20 observations made during the later periods of the disease, sloughs being actually present in the stools in some instances, in one only was a positive result obtained, and in this case a relapse very shortly followed; though in the three cases in which the examinations were made before the seventeenth day in each the typhoid bacilli were demonstrated at the second attempt.

[67] Annales de l'Institut Pasteur 1895, p. 252.

It would be wrong, of course, to assume that because the micro-organisms cannot be demonstrated by our imperfect technique after the beginning of the third week that therefore they are not present. We have seen, indeed, that the gall-bladder may contain a pure culture of typhoid bacilli at the patient's death late on in the disease, and as a matter of fact this condition may continue for weeks, months, and even years after the primary attack. Whilst this lasts we must assume that the specific germ is carried with the bile into the alimentary canal, and we might therefore expect to find it in the fæces. It is possible, however, that if present only in small numbers the typhoid bacilli may be rapidly destroyed as soon as they come in contact with the other micro-organisms in the alimentary canal, for the toxines of not a few of them are extremely inimical towards the typhoid bacillus. This, however, though possible, has not yet been actually proved, and at present the following are the facts of which we are in actual possession. The specific micro-organism can be demonstrated in the stools if care be taken during the first and second and early part of the third week of the disease and possibly during the early part of the relapse. Later it cannot be demonstrated by our present methods. It follows, therefore, that the fæces are highly infectious at the commencement of the disease and that later they become much less dangerous. How soon they become absolutely innocuous cannot be stated, but we must be prepared for the possibility of their remaining in some cases a source of danger for long periods after the patient is apparently well—as long, that is to say, as the bile continues to harbour the parasite. It is quite possible, indeed, that certain epidemics in which the sanitary conditions were at fault and in which no obvious case of typhoid fever had been previously imported may have been caused by cases of this kind—epidemics which must always have a high interest for us, since it was from a consideration of them that Murchison was led to formulate his belief that in some cases at least typhoid fever could originate *de novo* and which prompted him therefore to name the disease "pythogenic fever."

The urine.—Passing now from the stools to the urine, the other great secretion by means of which typhoid fever is spread—or, as I believe myself, the chief means—I will only say now that, unlike the fæces, the urine only becomes dangerous in one out of every four cases of the disease and that as a rule it is towards the end of the disease or during convalescence that this condition occurs. In one other point, too, we notice a contrast and that is that while it is always difficult to find the typhoid bacilli in the stools in the urine it is always easy, for when they occur they are nearly always in pure culture and not uncommonly they are present in such extraordinary numbers that one cubic centimetre may contain as many as 500,000,000 micro-organisms. The danger of such a constant supply needs no comment, though incidentally it shows that our means of protection against the invasion of the typhoid bacillus are much greater than is generally supposed.

CONCLUSION.

If, now, we consider the facts which have been brought forward in connexion with the bacteriology of an ordinary case of typhoid fever we obtain the following data. The typhoid bacillus can always be found in the stools in the early periods of the disease. It can also be demonstrated always in the Peyer's patches and the mesenteric glands. It does not, however, remain limited to these situations but very soon and in all cases passes into the blood (from which it can be very often isolated) and by means of which it is distributed to the most diverse organs. Thus it can be always found in the spleen and in the liver. It gives rise in the skin to the typical eruption. It is in most cases present in the marrow of the bone and in the bile. It is frequently present in the urine, and is not uncommonly found in the kidneys. Occasionally, also, it may be detected in the lungs and sometimes in other organs.

And now we may ask, How do these facts bear upon our conception of typhoid fever? The answer is clear. Any conception of the disease which regards it merely as affecting the alimentary canal only can no longer be maintained. On the contrary, so far from considering it as an intestinal disease pure and simple, we should rather look upon it as a *modified form of septicæmia*. It is septicæmia in that always and in all cases the bacilli pass into the blood and then into the various organs, and in that the symptoms, excepting as far as they are intestinal, are referable to the poisons there produced. It is a modified form, however, in that in nearly all cases there is a definite local and primary disease whence the secondary dissemination of the micro-organism takes place.

Looked at in this way we have a ready explanation of the fact that the severity of the disease bears no relation to the number and character of the intestinal lesions. For just as a fatal septicæmia may originate in a scratch, so one or two small typhoid ulcers may be quite sufficient to allow the entry of the micro-organism and the development of the disease.

Three Lectures

ON

THE SURGERY OF THE STOMACH.

Delivered in the Theatre of the Royal College of Surgeons of England on March 5th, 7th, and 9th, 1900,

BY A MAYO ROBSON, F.R.C.S. ENG.,

MEMBER OF THE COUNCIL AND HUNTERIAN PROFESSOR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND; EMERITUS PROFESSOR OF SURGERY IN THE YORKSHIRE COLLEGE; AND SENIOR SURGEON TO THE LEEDS GENERAL INFIRMARY.

LECTURE III.[1]

Delivered on March 9th.

DILATATION FROM ATONY DUE TO VARIOUS GENERAL AND LOCAL CAUSES, AND PERSISTING AFTER THE ORIGINAL CAUSE HAS DISAPPEARED.

MR. VICE-PRESIDENT AND GENTLEMEN,—There are certain cases of dilated stomach of the atonic variety in which the chief symptoms depend on the great bulk of the organ. As descriptive of the amount of paralytic distension that is possible Bamberger mentions an extreme case in which the stomach held 70 pints of fluid.[2] As these cases may be dependent on chronic catarrh or on some general cause not mechanical it is not necessary that I should enter fully into the etiology or even into the treatment, for general and medical treatment if carried out systematically and for a sufficient length of time usually yields good results; but in some cases, despite regular lavage of the dilated organ, well-regulated diet, and general medical treatment, the dilatation persists and the nutrition of the patient and the general health become seriously impaired; in such cases the operation of gastrorrhaphy or gastroplication may be worth considering.

Bircher performed the operation and reported three cases in 1890 and Weir of New York published a paper on this subject in 1892 The reports show that the operation is a most beneficial one if the cases be well selected, but before performing gastroplication it should be clearly ascertained that there is no mechanical obstruction either at the pyloric orifice or in the duodenum, for in the report of a recent case

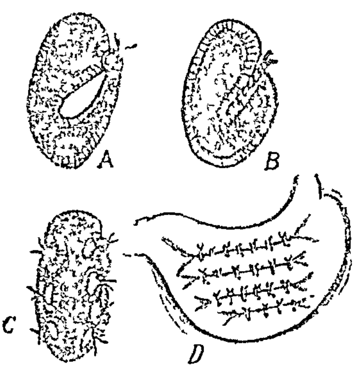
[1] Lectures I. and II. were published in THE LANCET of March 10th and 17th, 1900 respectively.
[2] Gould and Pyke, p. 630.

I noticed that gastrorrhaphy had been done where the pyloric orifice was markedly stenosed. Needless to say in such a case it could do no permanent good

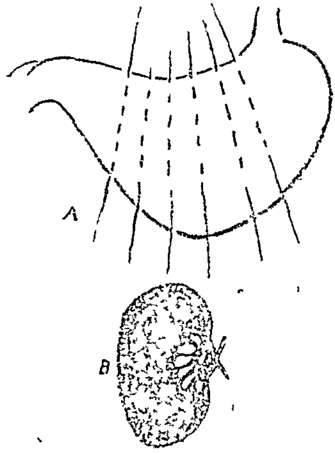
The following diagrams illustrate the method of folding and diminishing the volume of the stomach adopted by various operators In slighter cases probably Bircher's operation would do all that is required, but in the more severe cases a modification of Mr W. H Bennett's method would probably be the more efficient (Figs 5 and 6)

FIG 5



Different methods of gastroplication A Bircher's method seen in section. B Weir's method seen in section C Brandt's method seen in section D Brandt's method seen anteriorly

FIG 6



Gastroplication Bennett's method modified by Moynihan A, Seen anteriorly B A sectional diagram

The operation is neither difficult nor attended with serious risk since there is no danger of sepsis as the cavity of the stomach is not opened, and as the stomach can be drawn out of the wound to be sutured the general peritoneal cavity is saved from long exposure

The following table which Mr Willmott Evans has assisted me in compiling, I believe includes all the reported cases, 28 in number, with a 7 1 per cent mortality

TABLE XVIII.—*Statistics of Gastroplication (Gastrorraphhy)*

Name of surgeon operating or collecting cases	No of cases	Recovered	Died	Remarks
1 Bircher	1	1	—	The patient died a month later after pylorectomy.
2 "	1	1	—	The patient was well three years later
3 "	1	1	—	"
4 "	1	1	—	The patient was well two and a half years later
5 "	1	1	—	Later pyloroplasty was performed
6 "	1	—	1	The patient recovered from the operation but died two weeks later from syncope.
7 "	1	1	—	The patient was well a year later
8 "	1	1	—	The patient was well two months later
9 "	1	—	1	—
10 Brandt	1	1	—	—
11 Stockman	1	1	—	—
12 Bennett	1	1	—	—
13 Moynihan	1	1	—	The patient was well in 1899

Ibid, May 1898. 27 Terrier and Hartmann Chirurgie de l'Estomac, 1899 28. This case is reported here for the first time

I have only seen one case that I thought suitable for gastroplication and as the operation was only performed in January of this year it is too early to speak of it except to say that the patient, aged 35 years, who had been invalided for 18 months and who had tried lavage and other medical treatment for several years without benefit, expresses himself as cured of all his former symptoms and he certainly looks well and seems able to take his food without any difficulty I performed the [illegible] after [illegible] of the plan carried out by Mr P [illegible]

ACUTE DILATATION OF THE STOMACH.

Acute gastric distension was described by Dr. Fagge, his paper being illustrated by two cases, both in men, one 30 years of age and the other 20 years of age, and both ending fatally. The symptoms were those of largely distended stomach, coming on suddenly, accompanied by pain, diminished secretion of urine, and death. Many other cases of the kind have since been reported and the subject was fully discussed in an able paper by Dr. T. N. Kelynack[3] in the *Medical Chronicle*, where will be found a reference to all cases previously reported. Pepper and Stengel suggest that the immediate cause is spasm of the pylorus.

Carion and Hallion[4] have shown that the section of the pneumogastric nerves in the dog leads to dilatation of the stomach and to symptoms in many cases resembling those of uræmia. It seems probable that the symptoms are dependent on the absorption of toxins from the cavity of the stomach, just as in some cases the absorption from a dilated stomach leads to tetany. In a case of Sir William Broadbent's[5] eight pints of fluid were removed by the syphon. No sooner, however, was this removed than the stomach began to re-fill and rapidly regain its former dimensions. In the Leeds Infirmary we have had three cases of this kind, under the care of Mr. T. R. Jessop, Mr. W. H. Brown, and myself respectively, and they all terminated fatally.

Mr. Brown's case has been reported in THE LANCET.[6] In this case a man, aged 55 years, said to be suffering from intestinal obstruction, was admitted into the hospital. He was in his usual good health up to 48 hours previously, when suddenly he was seized with intense pain in the abdomen accompanied by incessant vomiting; the vomiting continued until three hours before admission. On admission the hands were cold, the pulse was small and thready, and the face was pinched and sunken. The abdomen was distended above the pubes, but flattened at the sides and epigastrium; it was resonant, except between the umbilicus and pubes, where it was dull. Fluctuation could be felt and a succussion splash was obtained. The temperature was subnormal. Earlier in the day the bowels had been moved slightly, but no urine had been passed since the onset of the illness—i.e., for 48 hours. The abdomen was not tender, but the patient was in great pain, turning from side to side constantly and asking for relief from his agony. A catheter was passed and about a drachm of bloody urine was withdrawn. An exploring syringe was passed into the fluctuating swelling midway between the umbilicus and pubes and withdrew about two drachms of thick greenish fluid with a curious smell recalling the contents of a pancreatic cyst As the general aspect of the case presented unusual difficulties with regard to diagnosis, and as it seemed certain that the man would die shortly if unrelieved and that the pressure of the fluctuating tumour was the cause of his suffering, Mr. Brown decided to operate. Ether was given and the abdomen was rapidly opened over the most prominent part of the swelling. A tense, thin-walled, rounded cyst was found which contained a dark liquid with some gas. As no colon could be seen or felt, and as the tissues of the cyst wall seemed to be more like peritoneum than any viscus, Mr. Brown drew it to the surface, opened it, and let out about three pints of dark green viscid fluid closely resembling that of a pancreatic cyst. The walls were stitched to the skin and the wound was closed. The patient rallied from the operation and expressed himself as being relieved, but he died five hours later. At the necropsy the cyst was found to be a dilated stomach which would easily hold five pints; there was no pyloric obstruction. The kidneys showed marked signs of nephritis and were saccular; all the other organs were healthy.

Mr. Jessop reported his case before the Leeds and West Riding Medico-Chirurgical Society; it also ended fatally after gastrostomy.

My own case came on ten days after a duodeno-choledochotomy for the removal of a gall-stone impacted in the common duct; the patient was doing well in every respect until 24 hours before her death when she suddenly began to vomit, the abdomen became enormously distended, the urine became suppressed, and the patient died in a state of collapse. At the post-mortem examination, beyond dilatation of the stomach nothing was found to account for death. It is interesting that in this case there were adhesions of the pylorus to the liver and gall-bladder which we thought might probably have been the cause of the trouble. I was unfortunately out of town at the time of the catastrophe, otherwise I should certainly have operated, though probably the result might have been no different, and when my colleague who was taking charge for me was called in to see the patient she was pulseless and cyanosed.

Dr. Appel[7] has reported a case where acute dilatation of the stomach supervened on an abdominal injury. The abdomen was opened for what was supposed to be intestinal obstruction, but three-quarters of the abdominal cavity were occupied by a dilated stomach. The stomach was opened, giving vent to a quantity of gas and fluid, the incision being afterwards closed, but the second night after the operation the abdomen became distended as before and death rapidly ensued. At the necropsy nothing was found abnormal except the distended and dilated stomach. It was suspected that the great sympathetic abdominal ganglia might have been injured, but nothing was found wrong with them on examination. Fenger[8] reports a case of acute distension of the stomach five days after cholecystotomy. The stomach-tube was used giving temporary relief, but the patient died on the tenth day, that is, five days after supervention of the stomach symptoms. The necropsy showed nothing amiss except an enormously dilated stomach. Dr. Box and Mr. Wallace[9] report a case in a boy, 16 years of age, following on a blow on the epigastrium. Abdominal section disclosed a dilated stomach which was incised and emptied but in that case also death followed. Kirch[10] reports a case in a youth, 19 years of age, who made a supper of soup and beer which was followed by pain and uncontrollable vomiting. The stomach was washed out and five and a quarter pints of greyish-green fluid were evacuated. The next day another two and a half pints were removed by the stomach-tube, but the patient died in the evening from heart failure four and a half days after the beginning of his illness. At the post-mortem examination the stomach was found to have lost its normal shape and to have the form of a long dilated tube reaching from the left hypochondrium to the true pelvis and then turning sharply upwards to the duodenum.

A careful analysis of all the recorded cases of acute dilatation would seem to point to a neuro-paresis, probably associated with spasm of the pylorus, but so far surgery seems to have been of little avail in these cases and no treatment seems to have been of material service. Nevertheless we must not give up our efforts and I would suggest that in every case of this kind, no matter at what stage it may be recognised, unless the patient be actually dying, the abdomen should be opened and the stomach emptied and connected with the jejunum, thus providing for continuous drainage into the intestine. I believe that as yet this method has not been put to the test.

Although in the greater number of cases of stenosis of the pylorus requiring the surgical treatment a general anæsthetic may be given, it is well to bear in mind that if necessary, as in serious cases like those under consideration, the operation may be performed under local anæsthesia produced by Schleich's method. Herczel has reported two cases where he did gastro-enterostomy in this way, in both of which recovery was rapid. In another case which he did under a general anæsthetic pneumonia supervened and he believed that the anæsthetic played a prominent part in its production. Czerny has remarked that a certain number of patients submitted to stomach operations suffer from pneumonia owing to the predisposition caused by the cessation of abdominal respiration and the superficial character of the thoracic respiration on account of the pain in the wound caused by costal movement. I have on several occasions performed operation of the stomach successfully under cocaine where I thought the patient too feeble for general anæsthesia or where chest complications rendered chloroform or ether inadvisable and with very little pain, discomfort, or shock to the patient.

GASTRO-ENTEROSTOMY.

Gastro-enterostomy, or the establishment of a permanent fistula between the stomach and duodenum or jejunum, is one of the most useful of the operations undertaken on the stomach, since there are fewer contra-indications to this procedure than in any other stomach operation, and it is applicable not only as a means of overcoming obstruction but also for giving physiological rest to the organ. It may be performed for simple or malignant stenosis of the pylorus, for chronic or acute dilatation, for intractable simple ulceration, and for bleeding ulcer, and it has been done for severe gastralgia and inveterate chronic dyspepsia not yielding to medical treatment. It was first performed by Wölfler on Sept. 27th, 1881, for cancer of the pylorus, by Rydygier and Mastryski for simple stenosis with dilatation, by Doyen for simple ulcer, and by Hartmann on Dec. 10th, 1895, for hæmatemesis due to bleeding ulcer.

As the various methods employed for gastro-enterostomy are given so fully in various text-books it is needless for me to enter into details which would occupy more time than is at my disposal. I have performed the operation successfully (1) by simple suture, (2) by the aid of Senn's plates, (3) by the use of my bone bobbin, and (4) by the employment of the Murphy button. Of these methods I have no hesitation in saying that I prefer the use of the bobbin. The operation where the button is used being by a few minutes quicker than when the bobbin is employed may be in some cases preferable, though there is a drawback to its employment in the fact of the button not infrequently falling into the stomach and remaining there. This has occurred in three of my own cases. In consequence of this accident and for other reasons Professor Kocher has given it up, and I hear that Dr. Murphy himself has also adopted Laplace's method of suturing in this operation. Laplace's operation is performed by means of an ingenious instrument which coapts the opposing surfaces that have to be united so that a continuous suture can be applied around the opening before the final stitch is inserted. I have seen the operation done by one of my colleagues but I have not as yet employed it. Its great disadvantage seems to be the absence of direct union between the two mucous margins and the small opening for anastomosis.

The junction with the stomach may be made either into the duodenum or upper part of the jejunum, the latter being, as a rule, preferred because it is easier and less likely to cause soiling of the peritoneum, since it is so readily clamped by an elastic ligature The jejunum is easily found by pushing to the right or raising the omentum and passing the hand behind the transverse colon when the attached part of the jejunum is at once reached and a loop selected about a foot from the fixed point. The junction may be made either to the front or the back of the stomach. If to the latter a slit must be made in the transverse mesocolon and the junction made through that; if to the former the whole procedure can be effected outside the abdomen and with much less general exposure; hence I prefer to make the junction in front. There are, however, many different methods in vogue for making the anastomosis which may be classified as follows: 1. *Gastro-jejunostomy.*—(*a*) Anterior, in which the junction is made to the front of the stomach. (1) Pre-colic (Wolfler, 1881) in which the jejunum is brought over the colon, and (2) retro colic (Brenner, 1892) in which the jejunum is made to pass through the transverse mesocolon and the great omentum before reaching the anterior surface of the stomach. (*b*) Posterior, in which the junction is made in the posterior wall through a slit in the transverse mesocolon (Von Hacker, 1885). (*c*) After pylorectomy by any of these methods. 2. *Gastro-duodenostomy.*—(*a*) With great dilatation of the stomach a junction may be easily effected between it and the second part of the duodenum (Jaboulay, 1892). (*b*) After pylorectomy (1) end-to-end suture; and (2) posterior anastomosis after closing the open end of the stomach and duodenum (Kocher).

Among the modifications are (*a*) Paul's proposal to incise all the tissues at the proposed junction except the mucous membrane and to apply chloride of zinc to these, so that within 24 or 48 hours after the operation the two hollow viscera will be made to communicate by the sloughs separating. (*b*) Postinkow (1892) and Podrez advise making the communication by means of two crossed ligatures tied tightly, which makes the anastomosis within three or four days. (*c*) Gaston (1884) employed in a similar way the elastic ligature on dogs and McGraw used it successfully on the human subject in 1890. (*d*) In order to avoid regurgitation Kocher adopted a valvular method of uniting the viscera. (*e*) For the same reason Chaput made use of an H-shaped opening. (*f*) Sonnenberg made a valve by invaginating the stomach into the intestine. (*g*) Braun joined together the two arms of the communicating loop of bowel so as to establish continuity of the intestinal canal without the contents passing the opening into the stomach. (*h*) Lauenstein made a communication with an adjoining loop of bowel for the same purpose. (*i*) Wolfler and Rouse modified these operations by completely dividing the bowel and implanting the cut ends into the stomach and bowel respectively. Practically there are two methods employed, Wolfler's anterior and Von Hacker's posterior operations. After pylorectomy Kocher's method is undoubtedly the best. A study of statistics would seem to show that it matters little which method is employed, and the surgeon will select that which seems to him to be the easiest to perform. For my own part I prefer Wölfler's operation.

The whole operation of gastro-enterostomy may be done in from 15 minutes to 30 minutes. All the precautions mentioned under pyloroplasty should be observed, so as to guard against shock. If the patient is too ill to bear general anæsthesia the operation may be done under cocaine supplemented by a whiff of chloroform and ether if required. The following points should be observed in anterior pre-colic gastro enterostomy. 1 After finding the fixed part of the jejunum make the anastomosis from a foot to one and a half feet from it, so as to avoid strangling the colon and kinking the junction with the stomach. 2. Let the afferent part of the intestine be to the left and the efferent to the right. 3. Fix the intestine well beyond the point of junction so as to avoid a spur. 4. Silk of moderate thickness is the best suture. 5. Apply a pad of gauze behind the parts to be joined as well as around them, so as to avoid soiling the peritoneum. 6. In anterior gastro enterostomy it is easy, if thought advisable, to bring a small loop of omentum around the line of junction and thus to make the operation safer.

After treatment—Since the greater number of these cases do not come under the care of the surgeon until very late, it is advisable to carry out all the means of preventing and combating shock that have been described. As soon as fluid can be taken by the mouth a little may be given in repeated doses; for instance, a teaspoonful of champagne every quarter of an hour is often useful. Light feeding may be commenced on the second day, especially if the button has been used. If there be regurgitation into the stomach the bowels should be moved by enema if possible, and the patient should be raised in bed and the stomach washed out. If no relief should ensue the abdomen may be re-opened and an entero anastomosis established, as has been done by Ricard and Czerny with success.

The ultimate results of gastro enterostomy have engaged the attention of several observers. These are: (1) return of digestive functions, (2) disappearance of hyper-acidity in the ulcer, (3) relief of pain, (4) cessation of vomiting, (5) healing of ulcer, (6) arrest of hæmorrhage, (7) return of appetite, (8) increase in weight, (9) disappearance of inflammatory tumour, (10) lessening of malignant tumours, (11) new blood formation, (12) gradual lessening of the dilatation of the stomach, and (13) in cancer prolongation of life of from three to 15 months. Dr. Steudel gives the average prolongation of life after gastro-enterostomy as 12 6 months, some of the patients being alive four and a half, five, and five and a half years after operation, but as these were in all probability cases of simple character this cannot be accepted as altogether accurate, and the estimate of 7 to 8 months, when doubtful cases are removed from the malignant list, is much more likely to be correct. Considerable contraction evidently occurs in some cases after the use of the button (Steudel), and probably after every method a certain amount of diminution of the opening occurs in time.

In the compilation of the following statistics (see Table XIX.) and in the verification of the references I have had the kind and able assistance of Mr. Willmott Evans.

With regard to the method of operating—i e., by the anterior or the posterior operation—Haberkant gives the percentage mortality at 44 for the anterior and 42 for the posterior operation, and von Hacker at 50 for the anterior and 36 8 for the posterior, but Mehler gives it at 47 9 for the anterior and 65 2 for the posterior. On averaging these percentages it works out as 47 3 for the anterior position and 48 for the posterior position, so that it would seem to make little difference whether Wölfler's or von Hacker's method be employed. It will be noticed that the number of cases collected (1978) is large and that the mortality varies from 0 per cent. to 100 per cent., but that on grouping all the cases together the average mortality is 36 4 per cent. The results vary very considerably according to the nature of the case for which operation has been undertaken, as also in the earlier and later series of cases. Haberkant gives two periods of seven years each. In the first period the mortality was 55·9 per cent. and in the second period it was 39·3 per cent. Petersen (Czerny's Clinic) also gives two periods in simple cases, in which before 1895 the mortality was 25 per cent. and since 1895 it was 3 per cent. Chlumskiji gives three periods. From 1881 to 1885 the mortality was 65·7 per cent.; from 1886 to 1890 it was 46·47 per cent.; and from 1891 to 1896 it was 33 91 per cent.

As to the nature of the case Stendel (Czerny's Clinic) gives the mortality in gastro-enterostomy for cancer as 34·5 per cent. and in gastro-enterostomy for simple disease as 14 3 per cent.; and Haberkant gives the mortality in gastro-enterostomy for cancer as 43·5 per cent. and in gastro-enterostomy for ulcer as 25·5 per cent.

TETANY AND TETANOID SPASMS IN ASSOCIATION WITH GASTRIC DILATATION.

It does not appear to have been generally noticed that severe muscular spasms of a tetanoid character, in rare cases amounting to severe or even fatal tetany, are frequently associated with dilatation of the stomach, yet I have noticed tetanoid symptoms in so many cases of dilated stomach that I have come to look at it as a frequent concomitant of the disease.

An important paper on the subject by my colleague Dr. E. F. Trevelyan published in THE LANCET[11] shows very forcibly that fully developed tetany associated with stomach dilatation is a symptom of extreme gravity and that in such cases a fatal termination is to be feared in a considerable percentage of cases. To quote from Dr. Trevelyan's paper: "If the term 'gastric tetany' is allowed to include the milder as well as the severer cases—and there is no sufficient reason against this view—then the disease may turn out to be more common than is usually supposed. The transition between gastric tetany strictly so-called, tetany with gastro-intestinal symptoms, and ordinary tetany would seem to be a gradual one. The prognosis of tetany occurring in gastric dilatation is undoubtedly very serious; nearly 75 per cent. of the cases die. The largest mortality occurs in [cases] where the spasm in the extremities is associated with tonic spasm in the head and trunk muscles or with clonic spasm. If the very strict views are held as to the disease then the outlook is almost hopeless; thus of the 11 cases recognised by Frankl Hochwart only one recovered. There is a danger here, as in some other diseases, that the fatal issue is raised to be the chief criterion as to the nature of the affection." My own experience of tetany and of the severe muscular spasms in association with gastric dilatation leads me to think that we may possibly take a more hopeful view if the cases be treated surgically at an early period. The following cases will serve to illustrate my views. In the first case the tetany was so pronounced that the question of strychnine poisoning crossed my mind. In the second and third cases, though there were well-marked tetanic spasms, the cramps were limited to the extremities and the abdomen.

CASE 1.—A man, aged 34 years, was sent to me by his medical attendant in January, 1895, with a view to having something done in the Leeds Infirmary to relieve his condition. He had been suffering for five years from pain after the ingestion of food, with attacks of vomiting. Latterly his condition had become aggravated, the pains occurring from half an hour to one hour after each meal and being relieved only by vomiting, so that for the last six months he had had to give up his work as a printer. For some time before coming under my notice there had been very evident peristalsis from left to right in the epigastric region. Throughout the period over which his stomach symptoms extended his bowels had for the most part been very constipated, but there were occasional attacks of diarrhœa. During this time he had attacks of what he described as "cramps" in his limbs and especially in his legs. He had lost very considerably in weight, as in December, 1892, he weighed 9 st. 6 lb., whereas in January, 1895, his weight was only 7 st. 7½ lb. On examination there was found well-marked dilatation of the stomach, but the feature of the case which presented most interest in connexion with the present question was the occurrence while under observation of severe tetanic spasms, affecting almost all the muscles of the body. So extreme were these and so widespread—the muscles of the trunk and of the cervical region as well as those of the limbs being affected—that on Jan. 17th the question of possible poisoning from strychnine was raised. As palliative treatment of the stomach condition gave no relief the stomach was exposed on Jan. 24th and the diagnosis of cicatricial stenosis with hypertrophy of the pylorus was confirmed. Pyloroplasty was done, a bone bobbin being employed to ensure patency of the new pylorus. Recovery was uninterrupted, and although the cramps were present up to the time of operation he never had even a threatening of cramp afterwards. On Feb. 15th he was able to take a mutton chop for his dinner without inconvenience, and by March 2nd (five weeks after the operation) he had gained eight and a half pounds. Since then he has done very well, and two years after the operation he had quite recovered his strength and was working as usual, his weight then being just over what it was in December, 1892, and quite two stones above what it was at the time of the operation. There has been no recurrence of any "cramps" or of muscular spasms of any kind. In a letter I received at the beginning of 1899 he speaks of some slight symptoms which may have had their origin in some stomach disorder, but he adds, "You will please understand that I am a new man to what I was when you saw me last."

---

[11] THE LANCET, Sept. 24th, 1898, p. 791.

CASE 2.—A man, aged 24 years, was seen by me on Oct. 5th, 1897, in consultation with his private medical attendant, on account of severe painful cramps of the extremities and of the abdomen, with persistent vomiting. He gave the history of having had pain after food for several years previously and of having vomited blood, since which time he had never been well and had gradually lost flesh. For some little time before I saw him he had vomited every day unless the stomach was washed out; and from weighing over 10 st. he had diminished to a little over 8 st. There was well-marked dilatation of the stomach, but no pyloric tumour could be felt, and simple stricture of the pylorus was diagnosed. He was admitted to the infirmary some time in October, and on the 21st I performed pyloroplasty as the pyloric orifice would only permit the passage of a No. 10 catheter. The longitudinal incision in the pylorus was sutured vertically over one of my bone bobbins. Recovery was uninterrupted and from that time the cramps and vomiting ceased. He returned home within a month. On Oct. 23rd, 1898, I received the following letter from him: "It is with a grateful heart I write to thank you for the good received at your hands 12 months ago. I am thankful to say I have never had any trouble with my stomach since. I feel it my duty to acknowledge the good I received and also to thank you for your extreme kindness."

CASE 3.—A woman, aged 29 years, was sent to me from the east coast in the spring of 1895 suffering from severe pain in the abdomen associated with vomiting and loss of flesh; there was well-marked dilatation of the stomach and the pain always started on the left of the abdomen and passed to the right, on which side, just below the ninth rib, there was well-marked tenderness with rigidity of the right rectus muscle. Operation was declined and I did not see the patient until nearly the end of the year when she told me that the pain in the abdomen was excruciating and recurred every day. She said it was associated with severe cramp in the limbs, especially in the legs and thighs, and that at night she was kept awake by the pain. Vomiting of large quantities occurred daily and she was steadily losing weight and strength. Her symptoms began in 1888 and she had lost two stones in weight between that year and 1895. On Dec. 14th I opened the abdomen and found active ulceration of the pylorus which was adherent to the gall-bladder, liver, and abdominal walls, and was so much thickened as to form a distinct tumour. Pyloroplasty was performed after the adhesions had been separated. Recovery was uneventful and satisfactory in every way and she returned home within the month. She never had any return of the tetanic symptoms and a report sent to me in March was to the effect that she had gained flesh and was "well." In July, 1896, I saw her again for stomach symptoms but without much loss of flesh. In 1897 and 1898 the vomiting, the loss of flesh, and well-marked stomach splash showed that the pyloric trouble had recurred, and as I found a distinct tumour of the pylorus, which I believed to be simple inflammatory induration, I performed gastro-enterostomy in October, 1898. She made a good recovery and has been well since. A letter in December, 1899, states that she is quite well and has fully regained her weight. The interesting point in this case is that there was no return of the painful cramps in the limbs after the first operation.

Though tetany occurs apart from gastric dilatation—for instance, in children during teething, when it is frequently associated with gastro-intestinal disorders and not infrequently merges into general convulsions—and in other conditions apart from stomach disorders, yet tetany or painful muscular spasms of a serious character are so frequently associated with gastric dilatation that one cannot ignore the association and pronounce it merely accidental. It is curious that I have never seen the symptoms in other than dilatation due to simple causes, such as adhesions of the pylorus to the gall-bladder or liver, or stricture of the pylorus due to the cicatrisation of ulcers. I have never seen it in simple unobstructive dilatation or in dilatation due to cancer of the pylorus, though Dr. E. F. Trevelyan gives single examples of its association with both in his paper.

The immediate cause of tetany is perhaps beyond the scope of a surgical lecture, but as my views are based on clinical experience they may be worth relating. I have noticed that the exacerbations of the tetanic state (especially in the first case I have related) were always associated with a painful contraction of the stomach, and that when the wave of contraction had reached the pylorus the latter, which was previously incapable of being felt, formed a distinct hard tumour. The abdominal pain then became very intense and the tetanic cramps in other muscles came on, or if already present became intensified. From this sequence of events I have come to the conclusion that the cause of tetany is a double one: first, the absorption of some poison from the dilated stomach which increases the excitability of the nervous system; and secondly, a reflex effect produced by the painful contraction of the pylorus. The practical outcome of these observations is that where tetany or allied conditions are associated with gastric dilatation surgical treatment is well worth considering before the symptoms become so severe as to lead to the almost hopeless condition described in the report of some of the fatal cases.

INJURY OF THE STOMACH.

The stomach is so well protected by the chest wall and the surrounding organs that it is seldom ruptured from blunt force applied to the abdominal wall, though contusions and partial or complete rupture may occur from a blow or kick in the epigastric region when the stomach is full. The vomiting of blood, therefore, with pain over the stomach immediately following a blow may demand exploration. It would be wise, however, before resorting to operation to inflate the stomach, as if a rupture has taken place gas will escape into the peritoneal cavity and the liver dulness will disappear, whereas if the organ be unruptured the distended stomach will be clearly outlined through the abdominal wall. In case of doubt a small incision in the middle line above the umbilicus will speedily settle the question, for if the stomach is ruptured there will be an escape of odourless gas immediately the peritoneum is opened and in all probability blood-stained fluid from the stomach contents would also escape. Needless to say, in case of rupture no time should be lost in first arresting hæmorrhage and then closing the laceration and cleansing the peritoneum.

Gunshot and stab wounds of the stomach are not infrequent and there are now numbers of cases on record where the stomach has been perforated by a bullet and recovery has occurred. It must not be forgotten that if there is one wound of entry into the stomach there will probably be one of exit. In one reported case there were no less than three wounds in the stomach, two of which were sutured and the third, being undiscovered, led to death from peritonitis. In stitching up the stomach Lembert's sutures must be applied well beyond the wound at both extremities. Dr. George Woolsey[12] reports a case of a wound from a pistol bullet in the abdomen in which he had successfully sutured two wounds of the stomach, two of the transverse and two of the ascending colon, five hours after the injury. In all Lembert's sutures were employed. Mr. A. B. Johnson[13] describes an interesting case in a man, 35 years of age, whom he saw a short time after he had been shot. The bullet had not only passed through the stomach but had also wounded the jejunum, the colon, and the mesentery. He was able to close all the wounds and his patient recovered. In case of persistent hæmatemesis after injury the stomach should be opened if necessary, for it is possible, as in a case described by Dr. J. Hazelwood Clayton,[14] where the patient died as a result of a crush, for the mucous membrane to be lacerated independently of the external coats of the stomach. In another case, described by Ziegler, a cyst appeared two weeks after a buffer accident and at the end of five months an operation was performed successfully and a large cyst of the stomach covered by the peritoneum was evacuated of three litres of fluid.

[14] Brit. Med. Jour., March 24th, 1894.

The older writers relate numerous cases of successful treatment of wounds of the stomach, but in many of them, such as that of Alexis St. Martin, a fistula was left. Spizharny collected 61 cases of gastric fistula. Fallopius successfully treated two cases of penetrating wound of the stomach, and there are many other cases of old and recent dates that can be referred to. The case I related under exploratory operations, where hæmatemesis followed on a stab wound of the abdomen, shows how a severe bruise of the stomach may lead to violent hæmatemesis, without there being an actual rupture of the stomach wall.

Nearly all cases of spontaneous rupture of the stomach are due to ulcer or carcinoma; but we should not forget that there are a number of cases on record in which rupture has occurred from over distension. Arton reports a case in a negro, aged 50 years. Fulton mentions a case of rupture of the œsophageal end of the stomach in a child owing to distension. Collins describes a spontaneous rupture in a woman, 74 years of age; this was followed by collapse and death, and a necropsy showed a rupture two inches long about two inches from the pyloric extremity. The records of St. Bartholomew's Hospital contain the account of a man, 34 years of age, who for two years had been the subject of paroxysmal pain in the stomach. At the hospital he had an attack of vomiting after a debauch, and after a sudden attack of pain at the pit of the stomach he died. A ragged opening on the surface of the stomach near the cardiac extremity was found post mortem, there being no signs of gastric ulcer or cancer. Clarke[15] reports two cases, one in a Hindoo, 22 years of age, and another in a woman who was supposed to have died from cholera. Recovery probably never occurs naturally in these spontaneous ruptures, but there are many cases on record of recovery after stab wounds.

Perforation may occur from within, as in the case of sword and knife swallowers. A remarkable case of this kind occurred at Guy's Hospital in 1807. After death there were 30 or 40 fragments of knives found in the stomach, one of which had transfixed the colon and the rectum. Needless to say that in all these cases the sooner after the injury the patient is treated the greater will be the chance of recovery. The openings will require closing with a double row of sutures—a continuous catgut suture for the mucous membrane and Lembert's silk sutures for the peritoneum. The toilette of the peritoneum must be carefully performed. If the soiling be local this is best done by sponging, but if the peritoneal cavity has become generally soiled then the cleansing is best done by lavage.

CANCER AND OTHER TUMOURS OF THE STOMACH.

Cancer of the stomach, which is more common in men than in women in the proportion of two to one, may occur at any period of life from youth to extreme old age, but it is most commonly found between 50 and 60 years of age and it may be said to be a disease of middle or advanced age. I have had to perform gastro-enterostomy for pyloric cancer as early as 21 years of age and Dr. Norman Moore has recorded an instance of undoubted cancer of the stomach at 13 years of age. Habershon, in an analysis of 79 cases of cancer of the stomach, found the growth at the pylorus in 41 cases, along the lesser curvature in 11 cases, and at the cardiac extremity in 10 cases. Brinton found 219 cases of the growth at the pylorus out of 360 cases. Cancer is by far the most common cause of tumour of the stomach. Sarcoma occurs less frequently and usually at earlier periods. Dr. E. C. Perry and Dr. L. E. Shaw out of 50 cases of primary malignant disease of the stomach found sarcoma in four patients aged 15 years, 18 years, 38 years, and 67 years respectively.

Tubercle of the stomach is uncommon except in children affected with general tuberculosis. I have only operated in one case, in a girl of 12 years of age, who besides the pyloric stenosis due to tuberculous disease had stricture of the duodenum, general tuberculous disease of the stomach, and tuberculous peritonitis.

Fibro-myoma of the stomach is rare, but it may form a pedunculated growth projecting as a polypus into stomach, and if it be away from the pyloric extremity it m produce no symptom until its size demands attention.

Polypoid outgrowths of the mucous membrane which m be termed "adenoma" or "papilloma" are uncommon; in one case that came under my care a polypus of this nati was obstructing the pylorus, the obstruction being succe fully relieved by its removal.

Hayem[16] describes a new variety of gastric polyadeno which is constructed on the type of Brunner's glands in t duodenum. The varieties of polyadenoma of the stoma previously recognised are two—(a) those that are polypo and (b) those consisting of thickened folds of the muco membrane, the constituent gland tubes being grea lengthened but never invading the muscular mucosæ. Th form also commonly occurs in a nodule and is then oft associated with chronic gastritis and with cancer elsewhe on the stomach wall. Hayem describes two cases of aden matous growth resembling Brunner's glands, and chie affecting the submucosa. It appears to be derived from t glandular cul-de-sacs of the mucosa, but it rapidly pass through the muscularis mucosæ and develops in the su mucous tissue. This form of adenoma is related in interesting manner to gastric ulcer and to maligna disease. In the first of Hayem's two cases a man died from perforating gastric ulcer which was directly due to adenoma of this form. The adenoma gave rise to atrop and separation of the muscular coat, and then itself und went infective ulceration. In the second case, in which latent gastric ulcer had been succeeded by the developme of carcinoma, the pylorus evidently became acute obstructed by an adenoma of the type of Brunner's glan Hayem regards these adenomata as benignant tumou which, however, may become malignant, and he places the in a transitional stage between innocent and maligna growths.

The stomach may also be the seat of lipoma, lymp adenoma, villous growth, and secondly malignant tumou Fibroid thickening of the pylorus may form a tumour whi can with difficulty be distinguished from malignant growt and on two occasions I have performed pylorectomy in su cases under the impression that I was removing a cance Such a tumour is dependent on the deposit of lymph arou a pyloric ulcer. The lymph becoming changed into fibro tissue not only causes great thickening of the pylorus b leads to matting of the omentum around it and to puckeri and hardening of the tissues that in some cases can only differentiated from cancer on section or on microscop examination. The long-continued history of ulcer may the only guide to the diagnosis, but in this connexion it mu be borne in mind that a chronic ulcer may end in cancer.

The following specimens from the Hunterian Museum a good examples of various forms of tumour:—No. 2411A is cancer of the pylorus producing stenosis and is from woman aged 36 years; No. 2417 is a cancer of the cardi orifice with dilatation of the œsophagus; No. 2421 ar No. 2422 are cancers of the cardiac orifice with cancer of th œsophagus also; No 2426B is a colloid cancer of the pylor producing stenosis; No. 2407 shows a perforation of th stomach due to sloughing of a cancer and is from a woma aged 36 years; No 2408 shows a very small stomach wi thickened walls due to new growth; No. 2408C shows greatly enlarged stomach from cancer which caused death six months; No. 2405 shows polypi growing from the muco membrane of the stomach of a man, aged 76 years, who suffer from constant dyspepsia; No. 2405C shows a polypus ne the pylorus producing fatal intussusception of the duodenu in a man aged 21 years; No. 2405D shows a polypus near th pylorus (pedunculated papilloma) which caused death b vomiting in a woman aged 92 years; No. 2407A is a villo growth near the lesser curvature found post mortem in a aged woman; No. A2407 is a melanotic sarcoma, two-thir of an inch by half an inch in size, from a man, aged 31 year who had other tumours in his skin and his interior organs and No. 2427 shows a cardiac orifice obstructed by gumm which also involves the adjoining part of the liver. Th patient was a military officer, 48 years of age, who had ha symptoms for 20 years and who died from starvation.

Diagnosis.—When the symptoms and signs of ulcer of th stomach—with or without stricture but with tumour—ar found at or after middle-age the probability is that th patient is suffering from cancer. Cancer of the cardia extremity can seldom be felt until it has attained a considerable size. Unfortunately, cancer of the pylorus is often quite incapable of being distinctly felt until it has formed a fairly large tumour, though in most cases an indefinite sense of fulness and hardness leads to a suspicion of growth before it can be distinctly defined. The tumour usually moves up and down with respiration, and when the pylorus is free from adhesions it may be felt quite easily and well away from the costal margin. While in cancer of the cardiac orifice the stomach is usually contracted and small, in pyloric cancer it becomes dilated and the dilatation may assume such large proportions as to be the prominent sign. Inflation will not only enable an estimate to be made of the size of the organ but it will differentiate between a retro-peritoneal and a pyloric or stomach tumour, and will show the relation of the tumour to the stomach cavity. For instance, in a case which I saw recently I thought the tumour from its size and position to be one of the body of the stomach, but on distension with air I found it to be pyloric; and another that I believed from palpation and percussion to be a growth involving the cardiac extremity I found to be a tumour of the centre of the stomach with a dilated cardiac portion sufficient to permit of a gastro-enterostomy being performed. In cancer of the head of the pancreas there are *usually* jaundice and a distended gall-bladder, and inflation will show the relation of the stomach to the tumour The bleeding in cancer of the stomach is usually shown as grumous vomit, seldom as a large hæmatemesis as in ulcer, and melæna is seldom found. The pain is more constant than in ulcer and not so distinct after food. It may be absent, but in one form or another is present in 90 per cent of cases and is usually very severe. On examining the stomach contents after a test meal the absence of free hydrochloric acid is very suggestive of cancer, as is the presence of free lactic acid, but the presence of free hydrochloric acid does not negative the existence of cancer. Loss of flesh occurs from the outset and cachexia supervenes at an earlier stage than in cancer elsewhere. It would seem almost incredible that cancer of the stomach may exist in a latent form and produce death by exhaustion without any of the characteristic symptoms, but I have seen a case of this kind in a man, 70 years of age, and others have reported similar cases Before a tumour is felt there may often be a difficulty in diagnosing between pernicious anæmia, tubercle, and cancer of the stomach, but when persistent indigestion comes on after 50 years of age for the first time it is very frequently due to cancer. At times carcinoma can only be diagnosed by the resistance present when the patient is deeply anæsthetised

Prognosis.—As medical means can do nothing more than relieve the symptoms of cancer of the stomach, and as surgery holds out the only hope of relief or cure—moreover, *as the earlier these cases are* seen by the *surgeon* the greater is the probability of real good being done—it would seem to me that in every case where cancer of the stomach is suspected the question of surgical treatment should be considered at a much earlier period than is now the custom. It is unjust to the surgery of to day to dismiss the treatment of this terrible disease in one page, as is done by the writer of an article on the subject in a recently issued and much read work on medicine It is an important fact bearing on the future of cases operated on that out of 38 cases of cancer of the stomach collected by Dr. Perry and Dr Shaw in 18 per cent. there were no secondary deposits found in other organs. Moreover, McArdle collected 1342 cases of cancer of the stomach of which 802 were limited to the pylorus, and out of this number 496 were suitable for operation. Gussenbauer and Weinwaster, as a result of the examination of the register of 542 cases of cancer of the pylorus, state that in 41 per cent there was no metastasis of the disease to other organs, and that in 37 per cent. there were no adhesions, so that one may reasonably hope on this evidence to perform a radical operation in one case out of three or four cases of cancer of the stomach if surgical means be adopted sufficiently early. The wisdom of the radical treatment of cancer of the stomach is not yet admitted generally even by many skilful surgeons, to say nothing of the opinion of the profession at large; but I think that a careful study of the subject will show that cancer of the stomach, *quâ* cancer, is more favourable for radical treatment than cancer of the breast or of the tongue or of many other parts where *its removal* is undertaken with considerable success because it is undertaken early, and now that the technique of the radical operation is becoming more perfect I venture to predict that we shall in the future give our patients the chance of relief by operation more frequently and that the aid of surgery will be sought as soon as the disease is recognised. We must bear in mind the fact that every life saved is a life gained, so that if we only save 50 per cent. of cases by the radical operation it is well worth doing, since patients with cancer of the stomach can only at the best have a miserable and hopeless existence unless treated surgically.

Before considering the statistics of the various operations an analysis of cases in which the radical operation has been performed for the cure of cancer of the stomach by Professor Kocher, Professor Maydl, and Czerny will show that the prognosis is not so hopeless as is generally supposed.

The following are the results of operations for carcinoma of the stomach in the Berne Clinic by Professor Kocher.[17] The author has resected the pylorus in 57 cases, the mortality being only 8 7 per cent., otherwise over 50 of the cases recovered. Of these one, a woman, is still living 10 years after the operation, another five years, a third three years, and a fourth two years. Four other cases died from accidental causes or from other diseases after three years had elapsed. The results of pylorectomy for malignant disease from the Heidelburg Clinic[18] up to January, 1898, show 24 operations with nine deaths, which *gives* a mortality of 37 5 per cent. Life was prolonged for three months, seven months, nine months, 10 months, 11 months, 15 months, 20 months, and 31 months respectively in those which recovered, and in four cases the patients were alive at nine months and 11 months and at three and a half years and seven years after operation.

Professor Maydl has published the results of 25 operations which he has performed for cancer of the stomach. For the sake of comparison he divides these 25 cases into three groups The first group comprises cases in which the patients died from the effects of the operation either directly or indirectly. These were four in number. The second group includes those dismissed from the hospital as "cured," but in which within a short period thereafter a recurrence of the disease took place and death ensued. These were seven in number. The third group, which is the most important, comprising 14 cases, included those cases in which the patients still live This section he divides into sub-sections: (*a*) those patients who were living upwards of two years after operation, and (*b*) those patients who were alive less than two years after the operation. Of the first group four died—one from a sudden attack of gangrene in the right lower extremity, probably embolic from the tying of a vein, but this could not be confirmed as it occurred in a private patient and the friends declined to consent to a post-mortem examination. The other three died in two, three, and five days respectively after the operation from peritoneal *symptoms* and collapse with anæmia and exhaustion. The second group left the hospital in good health and apparently cured, but ere long had recurrence elsewhere and died. One of the seven cases may be looked upon as doubtful. This patient lived for 14 months after the operation and died from pleurisy with effusion, every other organ being found healthy at the necropsy Even the appetite was unimpaired up to the very end and no disease could be discovered in or near the stomach. The other six cases lived for 12 months, eight months, two months, 20 months, 14 months, and 12 months respectively after the operation, or *on an average for 11 3* months. Of the third group 14 are still alive. These were operated on on August 27th, 1890, on June 7th, 1893, on Jan. 27th, 1895, on March 1st, 1896, on March 20th, 1896, on Feb. 25th, 1897, on March 27th, 1897, on Jan. 30th, 1898, on Oct 29th, 1898, on Oct 31st, 1898, on Nov. 3rd, 1898, on Dec. 21st, 1898, on Jan. 4th, 1899, and on March 25th, 1899, respectively. If these be further sub-divided into two groups of over and under two years we get the patients who may be considered cured in the surgical sense of the term. Seven cases may be classed thus—eight years and eight and a half months, five years and 11 months, four years and three and a half months, three years and two months, three years and one and a half months, two years and two and a half months, and two years and one and a half months

In considering the percentages the above figures of Professor Maydl give 16 per cent. as the [illegible]rtion of those who die from the operation. In [illegible] while 56 per cent. live. It [illegible]

Berlin condemned this operation on account of the mortality, he having had 73·3 per cent. of deaths, which was certainly not encouraging; but these results far exceeded those obtained by the pioneer of the operation, Billroth, who had a mortality of only 45 per cent. Billroth's pupil, Mikulicz, reduced this mortality to 32 per cent., while other operators—Kronlein, for example—had only 25 per cent., Carl and Fantino 45 per cent., and now Maydl's mortality stands at 16 per cent. and Kocher's at 8·7 per cent. The prognosis is at present much more favourable than it was in the past. In order to still further lower the mortality it will be necessary that patients be placed in the hands of the surgeon earlier than has heretofore been the case.

SURGICAL TREATMENT.

The treatment of cancer of the stomach may be radical or palliative. Of the radical operation we must consider (1) pylorectomy, more or less extensive (partial gastrectomy); (2) almost complete gastrectomy; and (3) total gastrectomy. Of the palliative means there are: (1) gastrostomy; (2) Bernays' operation; (3) gastro-enterostomy; and (4) jejunostomy. As each operation requires careful consideration I must take them seriatim. The first procedure will in all cases thought suitable for operation consist of an exploratory abdominal section and on the condition which is found will depend the after treatment. In Czerny's clinic there were 24 exploratory operations for cancer, with a mortality of 25 per cent., and the duration of life after operation was usually less than five months. I have myself performed eight exploratory operations for cancer of the stomach, and finding enlarged glands or secondary deposits have at once closed the abdomen. All the cases recovered from the operation and lived for various periods.

Preparation.—The bowels should be cleared either by an aperient or an enema the night before the operation, and the stomach should be washed out an hour or two before if the patient be in a condition to bear it. As these patients bear shock badly it should, if possible, be prevented. The operating-room should have a temperature of 70°F. and the patient should be enveloped in cotton-wool, which may be conveniently carried out by a long-sleeved jacket and long stockings made of Gamgee tissue. These were suggested to me some years ago by a lady on whom I had operated and she made me the first suit of cotton-wool clothes. They can be made by any nurse in an hour or two at a cost of a few shillings. An artificially heated operating table is an advantage, and if a specially heated table be not at hand an oblong water cushion filled with hot water or a series of indiarubber water bottles placed under the blanket of the operating table will take its place. An injection of 10 minims of liquor strychniæ, B.P., given before the administration of the anæsthetic, supplemented by another injection if necessary during the operation, is useful. An infusion of saline solution may be required, as in the gastrotomy for foreign bodies performed in 1894 and mentioned in my first lecture. The apparatus for transfusion should therefore always be ready as it can be used by a colleague while the operation is proceeding, or the saline fluid may be steadily injected in good quantities into the subcutaneous tissue of the axilla, either by means of a large syringe or by an ordinary aspirator needle connected with an indiarubber tube and glass funnel which can be easily arranged by a nurse and used continuously for a little time. After operation the patient should be placed in a warm bed and surrounded by hot-water bottles, and I always order a pint of warm saline fluid with an ounce of brandy to be injected into the rectum immediately after the operation, the injection to be repeated if the pulse seems to indicate its necessity.

Pylorectomy.—Pylorectomy, or the removal of the pylorus and as much of the adjoining part of the stomach and duodenum as may be involved, is an operation that was first demonstrated to be feasible on dogs by Merrem in 1810, but the first operation of the kind on the human subject was performed by Péan in 1879 and the first successful one by Billroth in 1881. The operation has been much modified since it was first performed, it being then done by suturing the open end of the duodenum, after removing the disease, to the open end of the stomach and closing by sutures the remainder of the stomach opening not fixed to the bowel. In one operation of this kind that I reported before the Royal Medical and Chirurgical Society in 1891 contraction of the newly-made orifice ensued some months later, and in order to avoid a like accident I modified the operation by employing a bone bobbin around which to join the open ends of the stomach and duodenum by sutures, thus securing adequate patency of the new channel.

As time is a very important factor in any operation on the stomach the rapid procedure of making the junction by means of a Murphy's button has found favour with many operators, though Professor Kocher speaks against its use. A further modification, and one which is now frequently followed, is to close completely both the stomach and duodenal openings either by a purse-string suture or by a double row of stitches, and then to connect the bowel to the stomach, making either a gastro-duodenostomy or a gastro-jejunostomy, whichever may be thought most easy and expeditious at the time. This will depend very much on the amount of stomach that has to be removed in order to get away the whole of the disease, for if much stomach has to be removed the open end of the duodenum will be less easy to fix to the stomach than a free loop of the jejunum. This operation is the one favoured by Professor Kocher and in his hands it has proved very successful. He uses strong forceps in closing the lumen of the stomach and bowel instead of employing digital compression, and he uses silk exclusively as a suture. Doyen's method of *écrasement* is very expeditious.

The performance of the operation *en deux temps* was suggested by Tupolske in 1891. He first performed a gastro-enterostomy and then, when the patient had recovered, he removed the pylorus three months later, closing the openings in the stomach and bowel and leaving the gastro-enterostomy opening to continue the communication with the intestine. This method has been followed by Quenu, Czerny, Hahn, Franke, Kümmel, Barker, and Doyen. It may certainly be advantageous in some cases where the patient is much exhausted and unfit to bear the longer operation of pylorectomy, as after the gastro-enterostomy strength will be gained and later the larger operation may be borne. The gastro-enterostomy may, however, give so much relief that the patient cannot be always brought to see the necessity of a second operation until it is too late to perform a successful pylorectomy. Haberkant's[19] statistics show that where adhesions were extensive the mortality was 72·7 per cent., whereas where there were no adhesions the mortality was only 27·2 per cent. Guinard's thesis shows a comparison between the results of the various methods of operating. In 148 cases of pylorectomy with end-to-end anastomosis the deaths were 56, or 37·8 per cent; in 64 cases of pylorectomy with terminal and lateral anastomosis the deaths were 10, or 15·6 per cent.; in 54 cases of pylorectomy with lateral anastomosis the deaths were 24, or 44·4 per cent; in four cases of pylorectomy by invagination the deaths were four, or 100 per cent; and in three cases of pylorectomy in two stages there were no deaths.

TABLE XX.—*Cases of Pylorectomy or Partial Gastrectomy.*

	Source of report of cases.	No. of cases.	Recovered.	Died.
1.	Billroth.	19	8	11
2.	Guinard.	299	194	105
3.	Czerny.	29	18	11

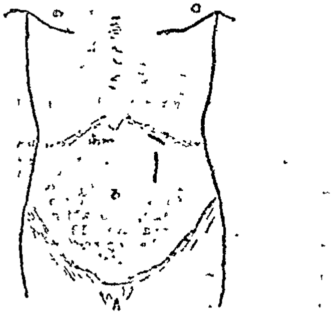
If the cardiac end of the stomach be involved the question of resection will be considered, and if decided on it may be carried out in the manner described by Levy. It presents two special difficulties—(1) danger to both pneumogastric nerves and (2) the difficulty of isolating the cardiac end of the œsophagus and fixing it to the stomach that is left. Levy[20] describes an operation devised by him, with the help of Fehlusen, for the resection of the cardiac end of the stomach. A rectangular incision is made through the abdominal wall, one limb running in the middle line from the ensiform appendage to the umbilicus, the other carried from the lower end of this through the whole breadth of the rectus muscle on the right side. The left half of the smaller omentum is separated from the stomach and the left coronary artery and vein are divided between two ligatures. After separation of the cardiac end of the stomach from the structures behind, the lower part of the œsophagus is isolated by dividing the serous membrane round this tube with scissors, exposing the anterior part of the œsophageal foramen in the diaphragm, and tying all visible vessels, mostly branches of the phrenic artery, at this part. At this stage there is a risk of wounding the pleura. The intestine being carefully protected by gauze the posterior wall of the œsophagus beyond the disease is stitched to a healthy portion of the stomach, and then the cardiac end of the stomach is divided by a succession of strokes, the cut edges of the anterior and posterior walls being stitched together after each stroke of the knife or scissors beyond the orifice left for the attachment of the œsophagus. This tube is now divided in a similar way, each portion as it is cut being stitched to the opening in the stomach. If the œsophagus be not fixed before it is completely divided it will retract and disappear above the foramen. The sutures are not carried parallel with the long axis of the œsophagus, but obliquely through its coats.

Gastrostomy.—If the disease has advanced so as to produce stenosis it will be beyond successful removal and gastrostomy should be performed, as in stricture of the œsophagus, in order to prevent the patient dying from starvation. Although Sédillot performed the first gastrostomy in November, 1849, the first successful operation was done by Mr. Sydney Jones on March 23rd, 1874. To Mr. H. G. Howse must be given the credit of greatly improving the operation by operating *en deux temps* and by splitting the fibres of the rectus so as to get a modified sphincter. The operation, however, has been, and is even yet, I fear, with many physicians still looked on as such a formidable procedure that even where it is strongly indicated the medical attendant frequently views it with so much disfavour as to lead him to discountenance its performance and to trust to sustaining existence in irremediable dysphagia by nutrient enemata Death from starvation under such circumstances is, however, one of the most terrible experiences both to the patient and his friends.

Why has the operation of gastrostomy acquired this ill repute? In the first place because it was, and even yet is, as a rule, customary to defer it until the sufferer is so reduced by starvation and so enfeebled as to be unable to withstand the shock of any operative procedure. Even if he does not die from shock, his healing powers are so impaired as to lead to failure in union and then to death from wound complications; or his assimilative powers are so impoverished that even if the operation be immediately successful death ensues from exhaustion. In the second place, where a direct opening is made into the stomach the fistula in many cases speedily enlarges and becomes patulous, leading to leakage of food and of irritating gastric secretion, so that the skin of the abdomen tends to become excoriated and the prolongation of life is attended with considerable discomfort. Do these conditions still apply? I think I shall be able to show that if the operation be performed sufficiently early, and if it be done according to the best methods, it will be found that gastrostomy may be included among the most useful and beneficent of the palliative operations which the surgeon is called upon to perform. When abdominal section was attended with a high rate of mortality it was only natural that delay should occur in advising operation; but if it can be shown that early operation is not accompanied by mortality or that the mortality-rate is only a slight one, due to accidental or unforeseen complications, it will be justifiable to perform gastrostomy early, knowing that the small opening will close voluntarily if the cause of the dysphagia should disappear or be cured by treatment.

The operation which I am accustomed to perform is very simple and only occupies a few minutes; it is a modification of the Ssabanejews-Franks method, but it differs in several details. A vertical incision of about one and a half inches is made over the outer third of the left rectus abdominis, commencing three-quarters of an inch below the costal margin; the fibres of the rectus are separated, but not divided, to the extent of the incision and the posterior part of the rectus sheath and peritoneum are divided together, the opening being an inch in length. A portion of the cardiac end of the stomach is then brought up through the wound and held forward by an assistant until four sutures are inserted into the base of the cone by means of a curved intestinal needle, so as to fix the visceral peritoneum of the stomach to the edges of the parietal peritoneum. A transverse incision of half an inch is then made through the skin, one inch above the upper end of the first cut, and by means of a blunt instrument, such as the handle of a scalpel, the skin is undermined so as to connect the two openings beneath a bridge of skin and subcutaneous tissue. A closed pair of pressure forceps is introduced through the upper incision as far as the projecting part of the stomach *and made to grasp the most prominent part, which it draws* up to and beyond the surface of the second opening, where it is retained by means of two hare-lip pins. It should just fill the opening and should require no sutures. The lower opening is now closed by two or three silkworm gut sutures or by a continuous stitch and the edges are dried and covered with collodion and gauze. If needful the stomach can be opened at once by a tenotomy knife introduced between the pins, but if possible the opening should be deferred for 24 hours, when a barrier of lymph will have been thrown out. After opening the stomach a soft catheter, from a No. 8 to No. 12, is inserted, to which a piece of tubing is fixed and by means of a funnel the patient can at once be fed with warm milk and egg or whatever liquid may be thought desirable. The catheter may be left in position for a few days, after which I find that it is easy to insert it whenever a meal is required. The annexed diagrams (Figs. 7, 8, and 9) will demonstrate the steps of the operation better than words and it can be done almost more quickly than it can be described. If the patient is much exhausted, an anæsthetic may be dispensed with and cocaine employed, as the only pain experienced is caused by the skin incisions. I have performed this operation in patients from one year of

FIG. 7.



Showing the position of the two incisions.

age to 86 years of age and with most satisfactory results.
Little or no shock is experienced, as although the peritoneum
is opened there is neither exposure of viscera nor handling of
any organ except the portion of stomach to be fixed, and I
have never known peritonitis to follow. Where the opera-
tion is not deferred until "too late" death should not occur
except from some accidental complication; for instance, I

patien ant stricture the patient gained his health and weight
hot-water and some time afterwards he regained the power
fluid with an little fluid, not sufficient, however, to support
immediately after thkes use of his gastrostomy opening for
if the pulse seems to indias a mere dimple to represent the
Pylorectomy.—Pylorectomy, or o which he inserts without
and as much of the adjoining part of catheter. There is
denum as may be involved, is an operand even after so
demonstrated to be feasible on dogs by Merlead or gastric
the first operation of the kind on the human subje wear any
formed by Péan in 1879 and the first successful one ocating,
roth in 1881. The operation has been much modified of the
it was first performed, it being then done by suturinptible
open end of the duodenum, after removing the disease, to the
open end of the stomach and closing by sutures the re-
mainder of the stomach opening not fixed to the hav
In one operation of this kind that I reported befo
Royal Medical and Chirurgical Society in 1891 contracene-
the newly-made orifice ensued some months later, rough
order to avoid a like accident I modified the operaby, the
employing a bone bobbin around which to join the owith the
thus enter the

stomach by blowing it through the tube, or it may be
aspirated into the stomach by the patient's sudden respi-
ratory efforts. Mastication of food as a preliminary step to
its introduction into the stomach satisfies, at least in part,
the sense of hunger which is not always accomplished
even by liberal exclusive gastric feeding through the fistula.
It is quite impossible in the time at my disposal to describe
all the modifications of the operation of gastrostomy, nor is
it here necessary to do so, as they can be found in the text-
books. I have performed the operation in various ways, but
have had such success by the method which I have described
that I can see no need to change it. The special methods
are: (1) Greig Smith's, (2) Frank's, (3) Witzel's, (4) Mar-
wedel's, (5) Kader's, (6) Paul's, (7) Jessett's, (8) my own
modification of Ssabanejew-Frank's, and (9) Hartmann's, &c.
The accompanying diagrams exhibited illustrate the chief
varieties better than words can do. I have said that I
prefer the method to which I am accustomed, but Greig
Smith's method, Frank's method, Witzel's method, Mar-
wedel's method, and Kader's method, all give good results.
The obturators suggested by Mr. Harrison Cripps, Mr. J. M.
Cotterill, and Mr. Bond, should not be required unless the
gastrostomy opening be too large and should leak. In a case
of cancer of the œsophagus on which I performed the opera-
tion suggested by the late Mr. Greig Smith my patient lived
for 11 months in comparative comfort, during the whole
of which time he never took a particle of food except by the
artificial opening.

A comparison of the results of gastrostomy in the fore
going table shows that it is impossible to state exactly the
death-rate of the operation, for practically in all the earlier
cases the patients died and in nearly all the latter cases
when performed sufficiently early they recovered. I do not
think that it would be an exaggeration to say that if cases
of incurable stricture of the œsophagus or of obstructive
cancer of the cardiac end of the stomach were handed
over to the surgeon at a sufficiently early stage the
mortality would not exceed from 5 per cent. to 10 per cent.
If the pylorus be extensively involved there will be dilata-
tion of the stomach, and if the patient be not in a fit
ondition to bear its removal, or if there be involvement of
lands or secondary deposits, a palliative operation only can
be performed. I do not think that Bernays's operation of
opening the stomach and curetting the pylorus in order to
make a larger channel is worth considering further, as it has

already been proved to give less relief than other operations, especially gastro enterostomy, and to be attended with danger of hæmorrhage and perforation

Jejunostomy —Should the disease be so extensive as not to permit gastro-enterostomy the operation of jejunostomy may be considered. I have performed it twice but as the operation at best can only prolong life for a very short time it is a procedure that cannot be strongly advocated The following case, in which there was extensive cancer of the stomach with inability to retain food, is a good example Jejunostomy was performed, the result being a recovery from the operation, but death from the progress of the disease at the end of two months

A woman, aged 58 years, was sent to me on June 19th, 1891, by Mr A A Hamilton of Crowle, on account of an abdominal tumour accompanied by persistent vomiting and rapid loss of flesh The patient was worn almost to a skeleton Occupying the left hypochondrium and reaching into the epigastrium was a hard nodular tumour, moving up and down with respiration, the skin being quite moveable over it A tumour could also be felt beneath the liver, which was diagnosed as a distended gall-bladder On July 1st, 1891, the A C E mixture being the anæsthetic and the skin of the abdomen having been asepticised, an incision of three inches in length was made in the linea alba above the umbilicus, exposing the tumour, which was found to be occupying the whole of the anterior wall of the stomach and to be incapable of removal There was also a distended gall-bladder containing gall stones The jejunum was then found at its fixed point on the left of the spine and traced for about six inches downwards, at which spot a knuckle of the bowel was brought forward and fixed by loop sutures in the way suggested for gastrostomy by the late Mr Greig Smith A loop of silver wire was first inserted into the convex surface of the bowel at a spot where it would have to be opened The rest of the parietal incision was brought together by interrupted silkworm gut sutures in the ordinary way On the following day the patient felt quite comfortable and was fed by the rectum entirely This was continued until the 7th, when a small opening was made in the exposed bowel with a tenotomy knife and a soft catheter was passed in, through which the patient was fed with peptonised food, of which she was able to take two or three pints a day She gained flesh and was able to return home on the 27th Her chief trouble was that the skin around the artificial opening became irritable but through the opening into the duodenum she continued to be able to take a fair quanity of food, which was well retained The original disease continued to advance and after two months she died from exhaustion No necropsy could be obtained

With regard to the operation of jejunostomy my experience would lead me to conclude that life can undoubtedly be lengthened by it in cases of cancer of the stomach too extensive for removal and where food cannot be taken; but it seems to me that it ought to be clearly stated beforehand to the patient that relief can only be hoped for and that existence under the circumstances may not be particularly comfortable, although life may actually be prolonged for weeks or even for months An opening into the jejunum for feeding purposes is quite different from an opening into the stomach and is not nearly so satisfactory, as the edges of the fistula tend to become irritated by bile and intestinal secretion producing considerable discomfort Maydl has proposed a modification of the operation of jejunostomy by cutting across the jejunum, suturing the proximal end into a slit in the side of the distal portion and then fixing the cut edges of the distal end to the skin The operation can also be done by the same method that I have advocated for gastrostomy In my next jejunostomy I propose to perform the operation through the rectus and to do it in every respect as in my modified operation for gastrostomy so as to obtain a small opening with a species of sphincter, in this way the mortality ought to be very small, as the operation could be performed in a few minutes and the retention of food should be complete

Gastro enterostomy —Of all the means for giving relief in obstruction due to cancer of the pylorus that cannot be removed, as also in many cases of simple stricture gastro enterostomy is an operation which is acknowledged by the greater number of surgeons as the most satisfactory procedure Some surgeons advocate this operation to the exclusion of all others and seem to justify their conclusions by showing good results both as to immediate safety and the length of time that the patients are relieved, but it must not be forgotten that gastro-enterostomy is merely palliative and therefore cannot be considered on the same level with operations that may prove curative by the complete removal of the disease In my last lecture I considered the operation of gastro enterostomy very fully in connexion with dilatation of the stomach from pyloric obstruction It is only necessary here, therefore, to refer to the results of gastro enterostomy for cancer and especially as to the probable prolongation of life by the operation

* Equals a mortality of 44 4 per cent.

References —1 Transactions of the Royal Medical and Chirurgical Society, 1892 2, 3 and 4 Greig Smith Abdominal Surgery 1896, p 550 5 THE LANCET Nov 26th 1898 p 1440 6 Allgemeine Medicinische Central Zeitung, 1897 No 58 7 Berliner Klinische Wochenschrift, 1896, No 60 8 THE LANCET Dec 4th 1897 p 1454

The mortality of gastro enterostomy is much greater in cancer than in simple ulcer—e g, Haberkant gives it in cancer as 43 6 per cent and in simple ulcer as 25 5 per cent Taking all collected cases together from reports by Mikulicz, Doyen, Carle D Ewald, Czerny, Chlumskiji, Haberkant, and others, I find that the mortality is 38 3 per cent It is rare for a patient with cancer to survive the operation for a year, and the average duration is probably only for from four to six months Later statistics are much better than the earlier ones and the results in cases operated on in time are really good The reason of the high mortality is undoubtedly the low state of the patient when placed under the care of the surgeon

Total gastrectomy —If the greater part of the stomach be invaded by growth and a careful examination of the adjoining parts reveals no secondary growths in glands or adjoining organs, complete or almost complete gastrectomy may be performed Although total gastrectomy had been proved possible in animals the first attempt to remove the entire stomach in the human subject was made by Connor in Cincinnati in 1883 but the patient died on the table, and it remained for Schlatter of Zurich to perform the first successful resection of the entire stomach for cancer in a woman aged 56 years on Sept 6th, 1897 After removing the organ Schlatter fixed the œsophagus to a loop of small bowel by sutures and closed the cut end of the duodenum Seven months after the operation the patient was well and had gained 6½ kilogrammes in weight, though she died at the end of 14 months from the time of operation The second gastrectomy was performed by Ch Brooke Brigham on Feb 24th, 1898, in a woman aged 66 years, the œsophagus being fixed to the duodenum by means of a Murphy's button In April the patient was well and had gained 6 lb in weight in the previous week, but she was still below her weight at the time of operation

The subjoined list (see Table XXIII) compiled by Mr Willmott Evans I believe represents all the published cases of complete gastrectomy up to the end of 1899

If the growth be limited to the body of the stomach partial gastrectomy may be done by a free circular or elliptical incision, the opening being closed by a continuous chromicised gut suture to the mucous margin and interrupted Lembert's sutures to the peritoneal coat, all bleeding points being previously caught up and ligatured

Partial gastrectomy —In many cases both of sarcoma and cancer the disease has advanced well into the body of the stomach and to get it away an extensive partial gastrectomy has to be performed In Langenbuch's case in 1894 he excised seven eighths of the stomach and sutured the pylorus to the small cardiac portion of stomach remaining, the patient making a good recovery. This operation has been repeated quite a number of times by others and with considerable success.

It seems advisable in these cases to close the gastric openings and establish a gastro-enterostomy with the remaining portion of the stomach, but the technique will depend on the amount of stomach removed and the state of the parts left: for instance, in Schuchardt's case the duodenum was united to the small portion of the cardiac end of the stomach, of the width of two or three fingers, that was left and the patient survived two and a half years and died from cancer of the pleura. It is interesting to note that in this case the portion of stomach left had, with the help of the duodenum, formed a digestive cavity with a capacity of 500 cubic centimetres and that the patient could digest ordinary food.[21] Mr. Charles A. Morton of Clifton read the notes of a successful case of resection of three-quarters of the stomach for malignant disease at the meeting of the British Medical Association on May 5th, 1889. The patient was a man, aged 39 years, who complained that for eight months he had had pain in the epigastrium and in the back after meals. He had vomited only occasionally. The patient was extremely emaciated but was able to take a little fish. On the left side of the abdomen above the umbilicus was a large, hard, irregular mass which varied in position and no certain diagnosis was formed. An incision of four inches in length was made through the abdominal wall and the growth was found to involve the greater part of the stomach, only the cardiac end being free. There were no enlarged glands or secondary growths. The omentum was ligatured and the stomach was turned upwards; then the gastro-hepatic omentum was tied and divided. The stomach was opened and a sponge placed in the œsophagus. The growth was then removed with the greater part of the stomach and the ends were closed by Lembert's suture. The duodenum was united to a fresh opening in the stomach by means of a Murphy's button. Drainage-tubes were left in temporarily. The patient recovered completely, but the button had not been noticed to pass. The growth was sarcoma. A case of extensive resection of the stomach for sarcoma in a woman, aged 52 years, is reported by Dr. Cantwell[22] of Texas, where after the excision of the growth the walls of the stomach were united by mattress sutures. The tumour weighed 12 lb. The patient made a good recovery, but a report eight months later said that there was a return of the growth. My colleague Mr. E. Ward has done three partial gastrectomies. In two of the cases the patients succumbed to the operation, but the first patient doubled her weight in three months.

In concluding my appointed task as Hunterian Professor I venture to hope that I have succeeded in demonstrating what an important relation surgery bears to diseases of the stomach, both simple and malignant. Fortunately, this class of disease is one where the improvement is readily seen both by the patient and his medical adviser, not only in the disappearance of painful and disabling symptoms, but by gain in weight. Hence a successful operation on a diseased stomach is one that yields peculiar satisfaction all round, and I can without hesitation say that I have had more expressions of gratitude from patients operated upon for diseases of the stomach than from any other class. I have tried to prove my points, not only by the relation of some of my own cases, but by statistical evidence gathered from all sources, and in the latter my work has been lightened by the kind assistance of Mr. Willmott Evans. I know how wearisome to the average reader is the study of tables of statistics, and I must apologise for introducing them so freely in these lectures, but I venture to think that they will be found useful for reference and to show, not only the actual risk of special operation, but also how great is the improvement that is taking place in the results of stomach operations generally.

I am proud to be able to say that my last 32 operations on the stomach in my private practice have all recovered, and I can see no reason why the success in this branch of surgery should not be as great as in the surgery of the gall-bladder, which now holds a very different position to what it did when I gave my first paper on the subject before the Clinical Society of London in 1885, nay, even to which it held when

---

[21] Beiträge zur Klinischen Chirurgie, 1897, vol. xix., p. 753.

[22] Annals of Surgery, 1899.

I lectured from this chair on diseases of the gall-bladder and bile-ducts in 1897.[23] In order, however, that surgery may attain to its maximum amount of success we must ask our medical colleagues for earlier diagnoses and earlier surgical consultation, so that if the case is one that can only be cured or relieved by an operation it may be performed before the recuperative powers have been lost. Then, and only then, shall we attain the ideal.

The Lettsomian Lectures

ON

PRACTICAL OBSERVATIONS ON CANCER OF THE BREAST.

Delivered before the Medical Society of London

BY SIR WILLIAM M. BANKS, LL.D.,
F.R.C.S. ENG.,

SURGEON TO THE LIVERPOOL ROYAL INFIRMARY; EMERITUS PROFESSOR OF ANATOMY, UNIVERSITY COLLEGE, LIVERPOOL

LECTURE II.[1]

Delivered on March 19th.

SOME POPULAR ERRORS IN DIAGNOSIS.

MR PRESIDENT AND GENTLEMEN,—There are some delusions about cancer of the breast in which almost the entire public still have faith, as have, I regret to say, not a few medical men. They are partly the result of text-book statements not properly explained and partly the result of popular tradition. They are difficult to eradicate because there is just that small amount of truth in them which makes it possible to argue about them. But they are very deadly and dangerous delusions because they cause loss of time, and, as we saw at the last lecture, that is destructive of the only chance of cure which science offers—viz., early operation. I would reckon among them errors about heredity, about pain, about cachexia, and about nipple retraction.

Error about heredity.—This question we have already discussed and need not further refer to, except to repeat that the absence of any cancerous taint among relatives is to a woman a very strong inducement to say nothing about any suspicious growth she may feel in her breast, because she comforts herself with the idea that it cannot be cancer as such a thing was never known in her family.

Error about pain.—This error is a most serious one. A few internal cancers, such as those of the liver and lungs, are sometimes almost painless in their whole course, but the termination of all external cancers, at all events, is invariably accompanied by severe suffering. These dreadful cases appeal so distressingly to the minds of women that they always associate pain with cancer. But unfortunately there are no neoplasms which produce less pain in their early stages than cancer. As the female mind, then, invariably associates the presence of pain with cancer, so its absence means to the patient that there is no cancer. If she has no pain in the lump and never heard of the disease among her relatives she is very unwilling to tell her medical man what she has in her breast. This remarkable absence of early pain is regarded as all the more of good omen by reason of the fact that in a large proportion of cases the patient discovers the lump in her breast by accident. Men do not, as a rule, wash their breasts very much, but women do, and certainly the most frequent way in which the patient tells the story of the discovery of her enemy is that it occurred as she passed her hand over her breast while washing So far from regarding pain as a sign of cancer, when a patient comes to tell me that she has detected something abnormal in her breast and that it is very painful, I am always glad to express my pleasure at hearing this statement, inasmuch as the disease is then probably not malignant. Pain in certain cases is by no means an evil.

Error about cachexia.—The error about cachexia is chiefly made by medical men. Often after examining a patient with some medical friend I have been struck by his remarking: "Well, but look at her ruddy colour and healthy aspect. There is no cancerous cachexia there." As in the case of pain, we have here an old superstition, a deeply-rooted popular belief to the effect that a patient who has cancer must have a pallid, emaciated, and haggard appearance. When fœtid discharge and agonising pain and sleepless nights and mental distress and absorption of septic products have done their work, then it is true that the unfortunate patient does present the appearance of a cachexia, but certainly not at the beginning of her disease. We have already noted that the victims of cancer are usually well-nourished persons, often with a fine healthy colour in their cheeks. Many a time I have pointed out to students in the out-patient room some jolly-looking, ruddy-faced man, with hair just turning grey, a big comforter up to his nose and a tuft of cotton-wadding sticking out of one ear, and I have said: "That man has cancer of the tongue." In cancer of the external parts cachexia is practically of no aid diagnostically, because in its early stages there is none, while in the later stages the growth is apparent. But I admit that in certain forms of intestinal and other internal cancers, where the symptoms are very obscure, the facts that the patient has lost his ruddy colour and has become pale and waxy, that his aspect is pinched, and that he has lost flesh and shrunk in his clothes—in short, the existence of cachexia—are important points.

Nipple retraction and skin adhesion.—Any error with regard to these can only be made by the practitioner and not by the patient, Perhaps the majority of text-books have hitherto somewhat misled the student on these points. It has been given out too broadly that retraction of the nipple is a sign of carcinoma, while the statement has not been sufficiently qualified by clearly indicating to the tyro that the sign is only of the least value when the disease happens to be situated immediately beneath the nipple. If the tumour has its site at any distance from the central point then retraction naturally does not occur. To persons thoroughly conversant with the matter it seems strange that it should be necessary to point out to anyone that the central point of the mamma can only be interfered with by disease that underlies that central point. As an actual fact, however, I know that the mere presence or absence of nipple retraction, without reference at all to the position of the cancerous mass, is too often appealed to by young practitioners. But if the absence of nipple retraction is no diagnostic sign in cases where the disease is situated away from the centre of the gland, it is, on the other hand, practically pathognomonic when it lies beneath it.

As we all know, adhesion of the skin is a very grave indication of a sub-lying cancer. It does not occur with any other tumour, except with an inflammatory swelling of the nature of an abscess. But there is a different appearance in the skin in the two cases. In the inflammatory adhesion the skin is fairly smooth over the abscess or whatever of an inflammatory nature underlies it. But over a carcinoma, if you try to pinch the skin up between the finger and thumb, immediately a number of fine points appear which are the hair follicles caught and tucked down by the cancer. It is exactly like the leather of a saddle, insomuch that I have always demonstrated it to students under the name of "pigskin." I regard this "pigskin" appearance as almost certainly indicative of subjacent carcinoma.

WHAT ARE THE CONDITIONS WHICH MOST CLOSELY SIMULATE MAMMARY CANCER?

Chronic mastitis.—To recount one's own mistakes is the most telling way of communicating information to others. I know that I have several times confounded a piece of chronic inflammatory induration with carcinoma. I can recall very clearly three cases. Curiously enough, the three patients were all married women between 35 and 40 years of age, comparatively spare in form and childless—a kind of person, by the way, who has always seemed to me more prone to chronic mammary induration than the stout, plethoric woman who has had a big family. When the condition becomes pronounced the whole breast comes to resemble a hard, flat cake. You can lift it off the pectoral muscle in a mass. Here and there throughout it are points of extra hardness, like knobs or bosses; one of these bigger than its fellows is the suspicious object. The question arises: Is that hard knob [illegible] of extra hard chronically indurated [illegible] as I mentioned in my last lecture, the statements of patients concerning the direct connexion of their cancerous growths with injury and the presence afterwards of slight pain or uneasiness at the point thereof have appeared to me to be worthy of more serious consideration than has been given to them and should not be dismissed at once as mere silly tales.

---

[23] THE LANCET, May 29th (p 1451), June 5th (p. 1525), and June 19th, 1897 (p 1666)

[1] Lecture I was published in THE LANCET of March 10th, 1900 Lecture III. will be delivered on April 2nd.

The principle of treatment of chronic mastitis by pressure, gentle friction, and the use of local remedies, such as used to be called "discutients," seems to be reasonable. I have a routine practice which is distinctly serviceable and which, I imagine, most practical surgeons employ also with variations. The patient is directed to bathe the breast for five minutes morning and evening with very hot water applied by means of a big cone-shaped sponge. Then there is rubbed into it mercurial ointment during one week and liniment of iodide of potassium with soap during the next week, the inunction being done with the greatest gentleness. After a while this treatment is apt to make the skin of the breast very tender and to produce crops of painful little pustules. It should be entirely left off and ointment of zinc should be smeared on until the skin irritation has subsided. Stays must be abandoned and the breast must be covered with a layer of cotton wadding. Pressure is applied by means of a broad elastic webbing bandage. The first turn is brought round under the armpits and fastened with a safety pin, and then the patient can pull on the remaining turns as they go down over the mamma as tightly as she can bear, fixing the bandage at the short ribs with another pin. The patient may take a moderate dose of iodide of potassium morning and evening, unless it proves very disagreeable to her; but after all it is without doubt in the local treatment that confidence is to be placed. Of course, I know that mercury and iodide of potassium are very old-fashioned remedies, but I still have belief in them and in their efficiency as "discutients" of chronic inflammatory indurations. But probably these simple views will not find favour with the practitioner of to-day for whom a new drug has to be provided once a week from the pill and capsule blast furnaces of America and Germany.

Only a generation ago the universal teaching was that an innocent or non-malignant tumour remained so always and never changed its character, while a cancerous or malignant one was so from its very earliest inception and never could be anything else. Surgeons have been compelled slowly to work themselves round to quite the opposite belief. It would almost seem with our present knowledge that with the exception of simple cysts and pure fibromata or myomata there is no neoplasm, however innocent in its commencement, which may not in time, perhaps after very many years, degenerate into malignancy. I have seen on two occasions even that most simple of all tumours, the lipoma, followed by what is called fat-sarcoma, requiring two or three operations of most extensive character for its extirpation.

Now, the degeneration of chronic interstitial mastitis into cancer is of course perfectly familiar to all operating surgeons. But I very much doubt if this knowledge is as thoroughly diffused throughout the profession as it ought to be, or rather I should say that I question whether medical men at large attach to it the immense importance which the matter deserves. A little while ago I said that I thought that attention might now be diverted from the devising of new operations for mammary cancer, for I believed that for the present they had in the majority of cases reached the limit of real use and that the whole energies of surgical teachers should be thrown into the propagation of the gospel of early diagnosis. For there is no more difficult case in the range of breast surgery than to know what to do with a breast, obviously the subject of chronic mastitis, in which among several very hard poin[illegible]re are one or two which are of such special [illegible] it is impossible to tell whether they have degenerated into [illegible] or not. My own practice is that if the preponderance, the [illegible] [illegible]derance, of evidence makes for nothing worse than chronic [illegible]s pure and simple, naturally the treatment above referred to [illegible] be at once put in practice, but even then the patient should be seen at regular intervals until all hardness is quite gone. For I have repeatedly seen the breast clear up from all induration, to the great delight of the patient, except at one spot, and there the cancerous limit had been reached and overpassed. When, on the other hand, the balance of probability is that the cancerous limit is being reached, even when to the touch no absolute certainty thereof is communicated, I have for many years practised and taught that removal of the breast is a justifiable proceeding. The way in which I have done it is by making a semilunar incision along the lower border of the mamma, dissecting up the skin and nipple, and laying them down again after the gland is removed, provided there is no sign that palpable carcinoma exists. How is this to be known? By cutting through any suspicious mass or nodule. I am quite sure that the section which an experienced surgeon makes with a knife through a fresh piece of carcinoma will enable him to give a far more decided and certain opinion than anything which the microscopist can give. Not that for a minute I would speak disparagingly of the value of microscopical examination. When it coincides with the naked eye view of the clinician so much the better, but when they differ I hold that the history of the tumour and the look and feel of the fresh section constitute the most trustworthy guide. An error may always be made by taking a microscopical section from a limited portion of the tumour where the process of growth is not actively going on. Moreover, there are inflammatory conditions of organs which so simulate in appearance certain malignant states that the ablest microscopist will admit himself unable to give a positive opinion about them. But the colour, the resistance to the touch, and the feel to the knife of a fresh mammary tumour section, however small that tumour may be, are the most certain guides of all as to its nature. With regard to the retention of the nipple and areola it must be remembered that they are to a woman the signs and symbols of a mammary gland which is a distinguishing feature of her sex. There are many women whose breasts when past middle life are so small and shrunken that but for the nipple and areola it would hardly be known that any breasts existed at all. I have an "impression" that chronic mastitis is more common in small breasts than in big ones, but it may well be said that this may arise simply from the disease being more easily detected in a small breast than in a big one. Still, having made a very great many naked-eye sections of cancerous breasts, the apparently sound gland tissue (away from the cancer) in a big, fat breast has rarely the tough hardness characteristic of a piece of chronically inflamed material. Referring again to the nipple and areola, if these be left to the patient she does not think so much of the loss of the gland itself. A man, similarly, will be quite content with a very wooden-nutmeg kind of testicle which is certainly useless functionally if only he be allowed to retain it in his scrotum as the badge of his sex. Assure the patient that her breast will not be materially disfigured and she will generally consent to anything to get rid of the haunting dread of that terror of her life—mammary cancer. But what if there should be more than mere mastitis? When the skin is being raised any suspicious point or points should be cut into, and if any one of these look cancerous then skin and nipple as well as the breast can be swept away too and the axilla cleared out, just as for an ordinary well-recognised case. A short time ago this very case happened to myself. Yet the patient's first shock of disappointment when she learnt what had been done was soon relieved by her satisfaction at feeling that she had been freed from her enemy. It is many years ago since I first proposed to the surgical profession that in every case of cancer where the breast was removed in the hope of ultimate freedom from disease the axillary glands should be removed as a necessary part of the operation. My argument was that it was impossible to tell whether they were involved or not, particularly in well-nourished persons. That argument has eventually prevailed over much opposition; and now to day I would desire to impress upon the profession that it is a right and proper thing in many cases to remove breasts the subjects of chronic mastitis even before cancer has been definitely diagnosed in them. The questions, and proper ones, at once arise, To what excesses may a doctrine like this not lead? What absurd and unnecessary surgery at the hands of the "enterprising surgeon" may not arise from this? Nay, may it not be a direct incitement to certain of the more needy class of surgeons to do operations for the sake of fees? I admit these possibilities, and yet I have such confidence in the good judgment and probity of the English surgeon beyond all other surgeons in the world that I believe yet the evil that may occur in this way will be far outcancelled by the saving of life affected by the removal of nascent [illegible] the a[illegible]. We know how absurdly overdone the removal of [illegible]ndix has been in some countries, until it became positively the subject of public merriment. And yet with all this misuse many lives have been saved by it, while the operation is meantime quietly finding its proper level and sphere of usefulness.

I have seen several cases of chronic mastitis in men and curiously enough they have all been in private practice. One of the things that, I think, produces it in them is the rubbing of braces and brace-buckles and these, of course, must be at once removed and a belt must be worn. The course of treatment above mentioned seems to be perfectly successful. One case of this nature occurred in the person of a healthy young man who was going abroad to a distant part of South America where he would be far from surgical assistance and that, too, if obtained, of a very poor order. Some few months before his departure he developed a chronic mastitis but did not take any notice of it as he had no pain from it. But very shortly before he was about to leave the swelling increased somewhat and he became very much alarmed in case anything dangerous should occur to him abroad in his out-of-the-way location. I told him that there was no time for any treatment and that the gland, which was a mere rudimentary and useless affair, could be removed with the certainty of a cure in a week. The removal was done by the semilunar incision, preserving *the skin, areola, and nipple so that no disfigurement resulted,* and he went away feeling quite happy in his mind.

At this stage the question naturally arises, If the transition from chronic interstitial mastitis into cancer is a thing the occurrence of which is admitted by all surgeons, can we guess in what proportion it occurs? Here it seems as if statistics were of no avail whatever. What attempts have been hitherto made have lost weight by reason of the fact that they have included all kinds of mastitic trouble. Now, my contention is that the mastitis out of which, or in which, carcinoma develops is of one kind and of one kind only—viz., the chronic interstitial mastitis which arises spontaneously about the middle period of life and has nothing to do with any previous inflammatory condition. Putting aside infantile and adolescent mammary abscess the only other acute inflammatory condition which arises in the breast of moment is milk abscess. It occurs in women during the active child-bearing period between the ages of 18 and 35 years When opened, drained, and cured all traces of inflammatory induration disappear in their sites. I have seen breasts the subjects of "rabbit warren" milk abscesses which I have literally cut in pieces which have healed so remarkably that the scars of them have been no great disfigurement, while the breast tissue has been as supple and soft as if nothing had been wrong with it. Again, in examining all kinds of female breasts for all sorts of trouble I have found the scars of incisions few and far between and of a very simple nature.

Mr. Bryant[4] says: "My own statistics tell me that out of my 360 cases of women who had borne children mastitis had occurred at some antecedent period in 80, but it is almost impossible to make out that the cancerous tumour originated at the seat of scar or induration. The tumour in the majority of cases appeared many years after the mastitis, even in one case 30 years." I cannot, therefore, agree with the statement copied from one book to another that acute milk abscesses leave behind them permanent indurations which degenerate into carcinoma or that the scars of incisions made for their relief are similarly dangerous. *Chronic interstitial mastitis* of the menopause—*voilà l'ennemi*

My friend and colleague Mr. F T. Paul has long studied this question and has an unrivalled collection of specimens illustrating it. It is from his stores that the most beautiful of the specimens which I shall show you to night have come and I hope that he will lay before the profession some day the results of his histological work. I would wish publicly to thank him for his courtesy and also my friend Dr. R. J. M. Buchanan (whose work on the Cancer Parasite will come into my next lecture) for the trouble which he has taken in arranging and preparing the lantern demonstration for to-night. Mr. Paul, like myself, while unable to fix a percentage believes most firmly that a much larger number of cases of chronic interstitial mastitis are allowed to drift into cancer than is commonly believed. The suggestion has been made and has been carried into practice by not a few surgeons that, where there is a doubt about the nature of a hard piece of chronic mastitis, the patient should be anæsthetised and that a piece of the tumour should be removed and subjected to microscopical examination. I have done this twice, but it does not seem to be a satisfactory proceeding, although theoretically it appears to be a very sensible thing to do. The truth is that what the patient dreads is chloroform and an operation of any kind. If the microscopist declares in due time that the disease is malignant then another chloroforming and another operation have to be faced. To everyone, and more especially to a woman, it is the prospect of a surgical proceeding that terrorises, and however much we may tell our patient that the removal of a small piece of her breast for examination is a mere trifle, to her it does not appear in that light, for she is no judge of the comparative severity of operations. In my first case I felt practically sure that the lump was cancerous, but the relatives were in doubt and would not allow removal until they were satisfied by the microscope that it was so. As the microscope did pronounce it cancerous the breast was duly removed and the patient had all the anxiety of the exploratory operation for nothing. In the second case the microscopic sections were so dubious in character that they were practically of no help and the diagnosis by the hand was just as good. It does not seem as if the exploratory examination will become popular. The best way is to tell the patient *and her friends the true state of the case* and the sources of doubt and to ask permission to proceed as you think fit on the strength of a naked-eye section made under an anæsthetic.

It is universally admitted that the essential feature of carcinoma consists in the escape of epithelium from the interior of the acini into the surrounding connective tissue and its subsequent proliferation there, this cancerous epithelium differing but slightly from the normal variety. It is clear that the ultimate reason for its proliferation must always be incomprehensible to us, involving as it does the principles of life and growth. Gland epithelium is always growing and always perishing and always being eaten up or discharged. So long as the balance between growth and waste is even there is health; when growth exceeds waste there is neoplastic disease. Apparently as soon as the epithelial cells escape from their normal habitat and get into the spaces that exist between the connective tissue fibres they increase at a great rate. Why? This is the crux of the whole question. Some hold that the irritation produced by parasitic bodies excites the growth of epithelium in ultimate alveoli or tubules and carries on the excitement when the epithelium has burst its bounds and has escaped into the cellular tissue.

In the *Journal of Pathology* of August, 1899, is detailed
very remarkable experiment by Dr. H. L. Lack. His view

[4] Diseases of the Breast.

normal epithelium into a lymph space or lymph cavity correct. In this condition we must leave the matter for the moment, acknowledging the almost startling nature of Lack's experiment but feeling that we cannot trust to a solitary example.

Let us see, then, if it be possible to trace the gradual development of a piece of carcinoma in a chronic interstitial mastitis. The earliest change probably consists in the appearance of quantities of leucocytes which constitute a round-celled infiltration distributed in the neighbourhood of the ultimate lobules. The single-layer epithelial lining of the tubules and acini which compose the ultimate lobules then begins to proliferate and grow into the interior of these cavities. At the same time there is a production of a new and very delicate connective tissue which surrounds the tubules and acini of each ultimate lobule. The normal connective tissue outside of that also increases largely in bulk, by reason of all which things many tubules are so squeezed and strangulated that, their distal portions being cut off, there is no exit for their contents, and they therefore become distended and form the innumerable little closed cysts which are found all through the cirrhotic breast of chronic mastitis. Matters may remain thus for long enough, the breast shrivelling more or less. This is the cirrhotic change already alluded to. But another change may occur. The growth of the epithelial cells in the tubules and alveoli may go on to such an extent that they become completely blocked up and appear as black areas on microscopical section. The fine interacinous connective tissue does not increase much in this case, but the ducts and acini, becoming more and more distended, eventually meet and fuse into each other. So that, in place of a number of small black areas we now see large ones, still giving slight evidences of the agglomerated acini of which they are composed. These masses of cells, however, are still held together by the surrounding interlobular tissue and by the limiting membranes of the original ducts and acini. But finally even these give way and the cells pour out into the strata of the connective tissue. They creep along between the bundles of connective tissue, following the tracts of what are probably the very earliest commencements of the lymphatic system, and rapidly reproducing themselves by the process of karyokinesis. They are now cancer cells, although between them and the original epithelial cells lining the tubules and alveoli there is not a great difference. There is certainly nothing absolutely distinctive. The normal glandular epithelial cell is of very regular shape and size and has one well-marked nucleus, being an orderly growing cell. The cancerous epithelial cell varies a good deal in size and shape, being a young, rapidly growing, erratic cell. There is some difference in the way in which certain stains affect with more or less intensity the cytoplasm of the two kinds of cells, but this is not improbably due to the difference in their age. Mr. Plimmer notices that in all actively growing cancers there is a zone of round-celled infiltration at the margin of the tumour where growth is most intense, and this zone does not exist in simple tumours. Near the more central parts of the tumour these round cells are converted into large mononuclear cells and later into fibrous tissue which surrounds the cancer cells. This stroma next causes a degeneration of the cancer cells, a digestive or phagocytic process. As time goes on the stroma hardens and serves the function of protection against invasion. So that the centre of a carcinoma is the hardest and most fibrous, and thus comes to pass the fact also that the harder the tumour—in other words, the more fibrous tumour there is in it—the less is the chance either of generalisation or recurrence. So, too, we arrive at the explanation of the atrophic cancer where he cells have been really all devoured by the connective issue. (These changes may be seen in the accompanying late.)

In the Transactions of the Pathological Society of London a very interesting paper by Mr. Cecil F. Beadles which has t been accorded the prominence which it deserves. It is certain histological changes found in association with ndular carcinoma. He examined microscopically nearly breasts which had been removed for primary carcinoma. came to the conclusion that 'breasts in which such ours are found are never in what may be called a nal state. It is often possible to make out with inger small, hard nodules situated at a distance he tumour and having no apparent connexion with it es, however, only slight thickenings can be felt in some parts of the breast. The acini show proliferative and other changes in the epithelium and there are to be noticed also changes in the stroma, which comes to resemble that seen in some rapidly-growing scirrhous tumours in which connective tissue-cells with their elongated nuclei run parallel around the acini, having between them what appear to be small uniform cells with round nuclei. The changes are both of the nature of chronic interstitial mastitis and, in the case especially of the thickenings and small nodules, of the nature of a condition intermediate between simple adenoma and carcinoma, extremely suggestive of commencing malignant disease. Mr. Beadles is of opinion that these changes in the apparently sound breast tissue are not produced by infection from the existing carcinoma but are most likely due to the same causes which started the tumour. Clinically and quite apart from all microscopical examination this is the opinion which I have always held myself—in plain language it means that there is a pre-cancerous state of the whole breast which, however, only blazes up into full-grown cancer at one or two points. It was this view which made me utterly disbelieve in the removal of the tumour alone and which prompted me many years ago to press vigorously upon the attention of the medical profession the advisability of free removal of the entire breast and with that the clearing out of the axilla.

Explanation of the Illustrations.—Chronic Interstitial Mastitis.

Fig. 1 represents chronic interstitial mastitis affecting a lobule. The lighter part with the dark area in it is a lobule. *a* shows tubules and acini of a lobule filled with proliferating cells, but they are being compressed by the growth of a young, fine, interlobular connective tissue *b*. *c* is the older interlobular connective tissue of the breast, also much hypertrophied.

Fig. 2 shows a much hypertrophied condition of the connective tissue, so that the glandular structure is almost squeezed out of existence *a*, atrophied gland tube and acini; *b*, large duct partially filled with cells with an empty one close by; *c*, hypertrophied connective tissue Cirrhosis

Fig. 3 at the upper part shows ducts and acini dilated owing to their compression by connective tissue at other parts. These produce the innumerable small cysts found in chronic interstitial mastitis. *a*, dilated ducts and acini; *b*, hypertrophied connective tissue; *c*, mass of acini with others close by produced by the proliferation of epithelium dilating them to such an extent that they press against each other and practically become fused. The lower part might become dangerous in time Cirrhosis.

Fig. 4 shows progression rather towards cancer than cirrhosis The old interlobular connective tissue *a* is considerably hypertrophied. The centre of the figure is occupied by the greater part of a lobule. There is no great overgrowth of young interacinous connective tissue. At *b* the acini are still separate, although filled with proliferating epithelium. *c* shows a large mass of cells formed by acini which have swelled out under cell pressure, have met, and then have fused The white holes, from which cells have dropped, evidence the sites of the former acini. The cells are still well limited.

Fig. 5 represents mastitis becoming cancerous. *a*, connective tissue; *b*, a lobule with acini filled with proliferating epithelium of which some has dropped out, not much interacinous connective tissue; *c*, masses of cells composed of fused acini still well defined; *d*, cells from a similar large mass bursting into the connective tissue and becoming cancerous at *e*. Cancer.

Fig 6 shows mastitis become cancerous. *a*, large fused mass of acini with two neighbouring ones (the central cells have degenerated and some have fallen out); *b*, cells escaping from this mass into the surrounding connective tissue. *Cancer.*

NOTE ON THE CAUSATION OF CANCER.

By Sir JAMES SAWYER, M.D., F.R C P. Lond,
F R S. Edin.,
CONSULTING PHYSICIAN TO THE QUEEN'S HOSPITAL, BIRMINGHAM.

Like Sir William Banks, whose admirable lecture[1] I have read with much interest and instruction, I have been in practice about a third of a century, and, as he has done, I have been led to form some decided "impressions" as to the etiology of cancer in our midst, he forming his ideas from a surgical standpoint and I from a medical one. While statisticians, clinicians, microscopists, and medical geographers are continuing their good work in adding to our knowledge of the incidence and pathology of cancer, and while we are not quite without increasing knowledge even of its successful therapeutics, and while we await the full light which research and observation will assuredly shed some day to make plain the causes and cure of cancer, in the meanwhile the impressions of thoughtful practitioners are of the greatest value as working hypotheses in preventive

---

[1] The Lancet, March 10th, 1900, p. 684.

practice. The probability of the truth of such impressions is strengthened when it is found that many minds arrive at the same conclusions. I have long thought that the accepted increase of cancer in England in recent years is due to the increased feeding of the population, and especially to increased feeding upon meat. It appears from the reports of the Registrar-General that the mortality from cancer in England and Wales has almost exactly doubled during the 31 years immediately preceding the year 1895. It also appears, as stated by Sir William Banks in his quotation from and summary of the figures of Mr. Haviland, that the increase in cancer mortality amongst us has risen more amongst males than amongst females If we desire to reason by the method of concurrent variations on the *causation of cancer we shall be led to inquire as to* what great and widely spread change has happened in the habits of life of the population of England and Wales during the last 30 years or so, and the fact of the enormously increased consumption of meat by the great masses of the people will be forced upon our attention. This generally increased consumption of meat has followed the continued importation of huge quantities of more or less fresh meat from America and from the antipodes. I do not mean that vegetarian feeders—if there be any who are strictly such—escape cancer. The intimate cause of cancer we do not yet know, but the malady has many of the features of a local overgrowth of tissue elements, and such appears to be favoured by excessive feeding and especially *by feeding excessively and for a long time upon meat.* In my experience cancer has not increased of recent years amongst the upper middle classes. In that class the general tendency seems to be towards refinement and variety of food, with the consumption of less meat and with slower and more complete cooking of meat than formerly; but for the men of the "masses" of our people meat is more a prevalent food than before, and with them meat is eaten in single dishes, in relatively large quantities, often, and undercooked. I think it likely it will be found that it is amongst the men of the masses in England and Wales that the progressive increase in cancer in the period under consideration is mainly to be found. Steam appears to have brought us cheap food, and cheap food has multiplied our cases of cancer *by two.*

Birmingham.

ON THE INFLUENCE OF THE TEMPERATURE OF LIQUID AIR ON BACTERIA.[1]

BY ALLAN MACFADYEN, M.D. EDIN.

THE experiments of *Dr. Horace T. Brown* and Mr. Escombe[2] have shown that no appreciable influence is exerted upon the germinative power of seeds when exposed for 110 hours to the temperature of liquid air (− 183° C. to − 192° C.). The results were *equally negative* in the recent experiments of Sir W. Thiselton-Dyer,[3] in which seeds survived exposure for upwards of six hours to the temperature of liquid hydrogen (− 250° C to − 252° C.).

The *following investigation on the influence* of the temperature of liquid air on bacteria was carried out at the suggestion of Sir James Crichton Browne and Professor Dewar. The necessary facilities were most kindly given at the Royal Institution. The experiments were conducted under the personal supervision of *Professor Dewar* and he has asked me to put the results on record, although it must be acknowledged that the essential features of the investigation are due to him. The bacteria employed were selected from the stock of the Jenner Institute of Preventive Medicine, where the results were also controlled. Pure cultures of the several micro-organisms were employed and the series included typical representatives of saprophytic and parasitic bacteria. The organisms chosen possessed varying degrees of resistance to external agents—the extremes in this respect being represented by the very sensitive spirillum of cholera Asiatica and the highly resistant spores of bacillus anthracis. Ten organisms were used for the experiments—viz, bacillus typhosus, bacillus coli communis, bacillus diphtheriæ, *spirillum choleræ Asiaticæ, bacillus proteus vulgaris, bacillus* acidi lactici, bacillus anthracis (sporing culture), staphylococcus pyogenes aureus, bacillus phosphorescens, and photobacterium balticum. The cultures of the organisms were young and vigorous and were tested both on solid and in fluid media—viz., nutrient gelatin, agar-agar, potato, and peptone broth. The cultures on these media were simultaneously exposed to the temperature of liquid air for 20 hours (− 182° C. to − 190° C.). They were then carefully thawed and examined. The results may be briefly stated. In no instance, whether on solid or in liquid media, could any impairment of the vitality of the micro-organisms be detected. The fresh growths obtained from the exposed tubes were normal in every respect, and *the functional activities of the bacteria were equally* unaffected. The colon bacillus produced its typical effects—such as the curdling of milk, the fermentation of sugar, and the production of indol; the staphylococcus pyogenes aureus retained its pigment-producing properties and the anthrax spores their pathogenic action on animals. The photogenic bacteria preserved their normal luminous properties. These photogenic properties are intimately connected with the functional activities of the cells. The cells emit light which is apparently produced by a chemical process of intracellular oxidation and the phenomenon ceases with the cessation of their activity. These organisms therefore furnished a very happy test of the influence of low temperatures on vital phenomena Their cultures, when cooled down in the liquid *air for 20 hours, became non-luminous, but on re-thawing* the luminosity returned with unimpaired vigour as the cells renewed their activity. Watery emulsions of the photogenic bacteria, on immersion in liquid air for a few minutes, ceased to emit light, but on withdrawal the luminosity re appeared in a very short time. Strips of filter paper soaked in the watery emulsion and brightly luminous were immersed directly in the liquid air with similar results. The sudden cessation and rapid renewal of the photogenic properties of the cells, despite the extreme changes of temperature, were remarkable and striking

The following experiment was made:—50 litres of the laboratory air about six feet from the ground were liquefied at atmospheric pressure in a glass bulb by means of boiling *liquid air in vacuo. The temperature reached was about* − 210° C. The bulb was then sealed off, the contents being still at a temperature below zero, and was subsequently opened and washed out with sterile broth A series of plate cultures were made from the broth on nutrient gelatin, agar-agar, and sugar agar, *and* were *incubated* under aerobic and anaerobic conditions at 22° and 37° C. for a period of ten days. The anaerobic plate cultures remained sterile. The aerobic plates yielded 44 organisms which had survived an exposure to − 210° C. The organisms were representative types of those to be usually met with in the air—viz., moulds, bacilli, cocci, torulæ and sarcinæ It may also be mentioned that a sample of yeast cell plasma (Buchner's zymase) subjected to *a temperature of from* − 182° C. to − 190° C. *for 20 hours* retained its peculiar properties unchanged—viz, as regards the production of CO_2 and alcohol.

The above experiments show that bacteria may be cooled down to − 190° C. for a period of 20 hours without losing any of their vital properties Further experiments are in progress with the above-mentioned, and with other micro-organisms exposed to the temperature of liquid air for still longer periods of time, as well as to that of liquid hydrogen. These experiments will form the subject of a future *communication.*

Chelsea, S.W.

ROYAL INSTITUTION.—The Friday evening discourse at the Royal Institution on March 16th was delivered by Sir Benjamin Stone, M.P., the founder and president of the National Photographic Record Association. The discourse was on the subject of Pictorial Historical Records and was illustrated by a large number of lantern slides showing views in Windsor, in Windsor Castle, and in the Tower of London, and antiquities in the Record Office. Modern survivals of ancient customs were also represented, such as well-dressing in Derbyshire, horn dance (with reindeer horns) at Abbot's Bromley in Staffordshire, mop or statute fair at Stratford-on-Avon, and the payment of "wroth money" to the Duke of Buccleuch on St Martin's Day in Warwickshire

PHOSPHATIC DIABETES.

BY GUTHRIE RANKIN, M.D. GLASG., M.R.C.P. LOND.,
PHYSICIAN TO THE SEAMEN'S HOSPITAL SOCIETY (ATTACHED TO THE "DREADNOUGHT" HOSPITAL, GREENWICH); AND ASSISTANT PHYSICIAN TO THE ROYAL HOSPITAL FOR CHILDREN AND WOMEN, WATERLOO ROAD, S.W.

THE demonstrable presence of phosphates in the urine is a clinical fact with which we are so familiar and which in its more usual manifestations is apparently of such little importance that we are apt to neglect it entirely as being an element of no more than passing and trivial interest. Phosphorus is essential for the growth and nutrition of the tissues, but the physiological part which it plays in the processes of metabolism is still imperfectly understood. It exists in a neutral form in the blood and is eliminated as a normal constituent of urine in the proportion of 1 part per 1000. The average daily excretion ought to amount to from 35 to 50 grains. It appears in the urine in three principal varieties:—1. The phosphates of potassium and sodium—the acid phosphates—are the chief cause of the acidity of the urine. They are extremely soluble and never form any part of the phosphatic deposit so frequently met with. 2 The phosphates of magnesium and calcium—the earthy phosphates—form about one-third of the whole normal phosphatic constituent of the urine; they are much less soluble than the acid phosphates and are precipitated if in excess on boiling or when the urine becomes neutral or alkaline. 3. Triple phosphates. These salts are formed by the combination of magnesium phosphate with carbonate of ammonia. The only source of ammonia is urea and therefore triple phosphates can only be found in urine which has undergone decomposition.

The occasional presence of phosphates which only become manifest on boiling the urine is not properly understood but is believed to be frequently concerned with undue wear and tear of the nervous system. The condition is not serious and disappears under the influence of rest combined with suitable tonic and dietetic treatment The persistent presence of phosphates which appear spontaneously as a more or less dense cloud in undecomposed urine of neutral or alkaline reaction is the rarest form of phosphaturia, but is also one which must be looked at suspiciously as capable of mischief. In this connexion it must be remembered that a spontaneous deposit of earthy phosphates in the urine is *not* necessarily evidence of their excess, because when normal urine becomes alkaline a deposit of phosphates may take place even when the amount of phosphorus eliminated is within physiological limits. Indeed, it has been frequently pointed out, first by Bence Jones and subsequently by others, that after the principal meals of the day the urine may become neutral if the character of the meal has been such as to lead to the formation in the intestines of large quantities of carbonates. The presence of triple phosphates at the time of, or immediately after, micturition is always indicative of local mischief in the urinary tract somewhere. All phosphatic deposits are at once dissolved by acetic acid and are thus distinguished from other forms of urinary precipitate.

The clinical importance of phosphaturia varies according to the chemical variety which the phosphorus presents in the urine. The temporary variety where the phosphatic salts are amorphous is not of present importance, nor is the local disorder which results in the production of the triple form of deposit; but the third variety in which the urine contains a deposit amounting, it may be, to a third or more of its whole bulk of stellar crystals of phosphate of lime is full of interest, not only because it is little understood, but also because it is rare and not infrequently fatal. In cases of this type the phosphates are present permanently in excess, but periodically the daily average of the amorphous salts is increased by a more or less copious shower of stellar crystals. The patient complains of thirst, polyuria, and languor. In cases where there is an increase of the urea as well as of the phosphorus emaciation may become a feature The urine is of low specific gravity and contains neither albumin nor until the later stages sugar; often not then. This form of phosphaturia was first called attention to by Tessier of Lyons in 1877 under the designation of "*diabete phosphatique*." It is usually met with either in young adults of neurotic heredity or in men at middle life who have lived freely, curtailed themselves of the requisite amount of sleep and relaxation, and pursued brain work under conditions where exercise was neglected and open air treated as a luxury. The disease may run a course symptomatically resembling diabetes mellitus but without sugar in the urine; or it may alternate with true diabetes, there being at some times an excess of phosphates and no sugar and at others sugar but no remarkable excess of phosphates. The initial polyuria may excite suspicion in the patient's mind and lead him to see his medical adviser, but if the case be one in which no sugar is found on application of the usual tests it is apt, and very naturally, to be looked upon as trifling and as wholly explained by a passing condition of nerve or digestive disturbance. Especially is this likely to happen if the urine chances to be examined at a time when the phosphates are only present in the amorphous form. As time goes on the patient's thirst increases, he is conscious of progressive failure of his general vigour, and not infrequently he is annoyed and puzzled by an unreasonable irritability of temper which is new to him. Neuralgia is a source of much misery in some cases, and may attack any nerve, but is specially prone to invade the branches of the trigeminal or facial; in others, the prevailing discomfort is a liability to recurring attacks of unaccountable drowsiness which no effort of will-power can shake off. When emaciation ensues there is always risk of the onset of phthisis.

Such is a short outline of the usual sequence of events in this variety of phosphaturia, and it is related to elucidate the following case which was recently under the writer's observation.

The patient was a medical man who had suffered for some years from kidney colic and had on more than one occasion passed a small uric acid calculus. He was of full habit, lived well, worked very hard, and abstained from every form of exercise. In the month of August he wrote to me: "Doubtless you are familiar with urinary deposits, but did you ever hear of a urinary scum? I have one, and I want to know all that is known about it, for it is attended with a remarkable symptom—sleepiness, not drowsiness, but prolonged, sound, pleasant sleep lasting for 12 or 14 hours. I have it about every six or eight weeks and there is positively no other symptom. I know exactly when I shall get it and as I slept last night and the night before nearly 12 hours each I knew I should have it this morning, and it is better marked than I ever saw it—quite a thick scum, so that I caught it easily on a slide. At first it is quite transparent and in an hour or so it glistens or iridesces on the top of the urine like oil, then solidifies like fat, just as you see it on the enclosed slide. At these times I have about from 100 to 110 ounces of urine in 24 hours, alkaline, with a specific gravity of from 1010 to 1018, and containing abundant phosphates. I have had chronic phosphaturia for some years, but cannot find out that it means anything." The deposit on the slide consisted almost wholly of stellar phosphates, with which were associated a few epithelial cells and one or two renal casts. A sample of urine was analysed two days after the receipt of the above letter and was found to possess a specific gravity of 1017 and to be neutral in reaction. It contained a trace of mucin, a haze of albumin, and an excess of uric and phosphoric acids, but no sugar.

At a later period this gentlemen again wrote to me: "No alteration occurred in my condition for several months, but I then had occasion to visit P——, and when there paid a visit to a farm owned by the gentleman who was my host. In the farm kitchen I saw some butter-milk and tasted it. A craze of the most extraordinary kind seized me at once—a feeling as if I could not do without it. I drank nearly three gallons that day and two the next, and so on as long as I could get it. I now travel with a quantity of it always and drink never less than two quarts a day, but without the intolerable longing for it. That has disappeared a month ago and so have the phosphates *absolutely*. I still have the abrupt violent polyuria as I have all my life. I have not gained in weight with the butter milk. During the craze I often took no solid food for 20 or 30 hours." This condition of apparent improvement continued till the following April when he again wrote: "I have but ill news to give you of myself. Three weeks ago the phosphaturia came back, has increased to an extent it never has reached before, and the butter milk is no good. My bladder is getting irritable and I evacuate every three or four ounces, often much less, with great heat and straining every time at the neck." At this date the urine analysis recorded an alkaline reaction, a specific gravity of 1015, a minute trace of albumin, no sugar, a large deposit of amorphous and triple phosphates, and some epithelial cells. A subsequent acute attack of renal colic was the prelude to a short illness in the course of which he had much trouble with his bladder, and which terminated fatally from sudden and unexpected coma.

The details of this case are so interesting and the record of symptoms is so graphic that I hope no apology is necessary for the length of the extracts which I have quoted. The entire disappearance of phosphaturia during the time he was taking butter-milk suggests that the acids which it contains so abundantly had probably something to do with neutralising the excess of phosphates, and if this be so it raises the question whether the large quantities of butter-milk which during his craze he was tempted to drink does not convey a hint that in the use of acids in ordinary forms of neutral or alkaline phosphatic urine we perhaps err in dealing with inadequate doses.

The presence of triple phosphates in the last analysis and the co-existence of pain, heat, and straining on micturition too clearly showed that the bladder had become the seat of a calculus, most probably a rapidly accumulating mass of phosphates outside a uric acid nucleus. He died comatose and this could hardly be ascribed to the condition of either his bladder or kidney. It more closely resembled the coma so often met with in diabetes mellitus. The urine was persistently excessive in quantity but it never contained sugar. If the uric acid element in this case be left out the picture of Tessier's phosphatic diabetes is almost complete. Most of the leading features of ordinary diabetes present themselves but the urine contains as its abnormal constituent an excess of phosphates instead of sugar.

Cases of this disorder are rare, but their diagnosis is easy if due attention is given to the urine, which is always neutral or alkaline in reaction, excessive in amount, usually of low specific gravity, and loaded with phosphates often of the stellar variety. The diseases with which it is most liable to be confused are diabetes mellitus, diabetes insipidus, and chronic interstitial nephritis. The urine of diabetes mellitus contains sugar and that of interstitial nephritis albumin, so that in straightforward cases either may be readily distinguished from the urine of phosphaturia. The latter condition, however, may occur in association with either or both of the former, when the urine will be found to contain phosphates, together with sugar or albumin, or with both.

The effect upon the general health tends to be ultimately serious and the prognosis should always be guarded. The occurrence of attacks of drowsiness, the onset of emaciation, the alternation of sugar with stellar phosphates, or a permanent increase in the urea excretion are the more important points which add to the gravity of the prognosis.

Treatment is summed up, according to Ralfe, in rest and improvement of the general nutrition. Drugs seem to be of little avail in checking the undue excretion of phosphates; even opium, which is of such value in true diabetes, has no effect and is, on account of the tendency to drowsiness, not altogether free from risk. Butter-milk may be added to the daily dietary and will be found of considerable nutritive value. This case suggests that it may also possess some direct power over phosphates when these are present in marked excess.

Chesham street, Belgrave-square, S.W.

CLERICAL, MEDICAL, AND GENERAL LIFE ASSURANCE SOCIETY.—The report of this society for the year ended June 30th, 1899, shows that the new assurances consisted of 810 policies, assuring £641,353, and yielding in annual premiums £21,797 Re-assurances were effected to the extent of £46,000, with annual premiums of £1741. The net new business of the year was therefore £595,353 in sums assured, yielding annual premiums of £20,056. The total premium income was £293,773, showing an increase of £5448 over last year, and the whole income of the society was raised from £422,006 to £431,776. The claims arising from the death of 235 persons, assured under 299 policies, were for the aggregate amount of £239,897. The excess of revenue over all expenditure amounted to no less than £106,900 and raised the assurance fund at the close of the year to £3,590,305. Three vacancies occurred in the board of directors caused by the death of Sir John Mowbray (the chairman) and the resignation of Lord Curzon and Lord Lister. Sir Thomas Smith, F R C S. Eng., was elected in Lord Lister's place.

A CASE OF IRREDUCIBLE DISLOCATION AT THE ELBOW.

BY R. HAMILTON RUSSELL, F.R C.S. ENG.,
SURGEON TO THE MELBOURNE HOSPITAL FOR SICK CHILDREN.

ON June 27th last a little boy, aged eight years, while playing at football fell with the left arm twisted under him and sustained a dislocation of both bones of the forearm backwards at the elbow. He was attended by Dr. Loosli of this city, who was at once struck by certain peculiarities in the case; he also found that all efforts at reduction, even under chloroform, were of no avail, and asked me to see the patient with him.

On examination the fact of dislocation backwards of both bones was very obvious, but there were unusual features which, as the accident is one that, so far as I can ascertain, is now recorded for the first time, I will describe with some minuteness. First, the arm was markedly straighter than usual—so nearly straight, in fact, that it had been found possible to put the limb up somewhat loosely in straight cardboard splints; secondly, there was an absence of the usual marked fixity of the arm, so that the forearm could be moved through a considerable angle but could hardly be made to approach so near to a right angle with the humerus as is usual in such a dislocation; thirdly, on attempting reduction, the sensation imparted to me was quite novel: the forearm yielded to the pull quite easily, and the deformity could be very nearly reduced but not quite, while directly the force was withdrawn the bones sprang back into their false position with a kind of elastic rebound. There was also occasional slight crepitus. I was unable at the time to make a correct diagnosis of the exact anatomical nature of the injury which produced these phenomena, but I advised, with Dr. Loosli's concurrence, an operation which was undertaken the next day.

Through a longitudinal incision over the extensor aspect of the joint the triceps and aponeurotic investment of the joints were divided and the interior of the articulation was exposed to view. It was then found that the interior was occupied by a mass of muscle which further investigation made evident as the brachialis anticus. The internal epicondyle was separated, which explained the slight crepitus during examination. The humerus at the time of the injury had pushed its way through the anterior ligament of the joint and passing to the outer side of the brachialis anticus had become lodged on the front of that muscle; so that when viewed through the operation wound the muscle lay strapped over the back of the lower end of the humerus and pinched tightly between that bone and the coronoid process of the ulna. It was necessary to divide a portion of the displaced muscle, and when that was done a strong curved spatula was passed between the remainder of the muscle and the bone and the humerus was easily pulled into place. The divided triceps was then sutured, the skin wound was completely closed, and the arm was put up straight in a stiff bandage. Six days later the bandage was taken off for the removal of the stitches. The wound was quite healed, and the little boy was able to bend his arm without assistance to near the right angle, in which position it was put up again in plaster-of-Paris for a further fortnight. Three weeks from the operation all apparatus was removed, but the child was directed to wear a sling for one week more, with permission, however, to take the arm out to use it when so inclined, but to return it to the sling when not using it; this was out of consideration for the partially divided brachialis anticus muscle. No passive motion was performed, although the elbow remained very stiff for some weeks. When last seen, five months after the accident, however, the movement had all returned and the result was perfect as to the utility of the arm, but on close inspection during flexion of the arm I had reason to think that the brachialis anticus had never completely recovered and that the other muscles passing from the condyles to the forearm and wrist were called upon for a somewhat larger share than usual in the production of flexion at the elbow. This seemed, however, to make no difference, as the child was able to play cricket and other games, and there was no perceptible weakness or defect in the limb.

HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

A CASE OF CHRONIC INTESTINAL OBSTRUCTION; NECROPSY.

(Under the care of Dr. D. B. LEES.)

INTESTINAL obstruction is a rare but very important complication of appendicitis. It is specially likely to occur in cases in which localised abscesses have formed and Hawkins[1] describes four deaths as due to this cause in ten fatal cases of local abscess; these are generally acute cases. Obstruction of the intestine, when chronic in character, if due to appendicitis, is more likely to result from matting together of the bowel[2] as in the case recorded below. In this instance it is not improbable that tuberculous disease of the appendix was the cause of the adhesions. Fitz[3] met with eight cases of perforation of the appendix resulting from tuberculosis in 257 cases of appendicitis. For the notes of the case we are indebted to Dr. Hugh Thursfield, medical registrar and pathologist.

A boy, aged two and a half years, was admitted into the Hospital for Sick Children, Great Ormond-street, under the care of Dr D. B. Lees, at the end of June, 1899. He was brought to the hospital on account of constipation and was treated in the out-patient department. The constipation was followed by a bad attack of diarrhœa for which he was made an in-patient The history given by his mother was that till the age of 18 months he was a healthy child, but he then began to suffer from attacks of diarrhœa. Three months later his stomach was noticed to be getting larger and the diarrhœa was now accompanied by abdominal pain. He was treated by a medical man and improved, but about Easter, 1899, he began to have attacks of abdominal pain in which the stomach was, as his mother said, "drawn up in cords." He twice passed blood by the rectum and vomited dark-brown fluid. He went to the country and improved for a time, but the abdominal troubles recurred and he was taken to the hospital As well as could be ascertained the family history and the surroundings of the child were fairly good, though his mother's father was stated to have died from "consumption"

On admission the child was very thin and fretful but had no fever and at first no diarrhœa; his appetite was fairly good and he did not appear to be very ill. The heart and lungs were apparently sound, but the abdomen was enlarged; there was visible peristalsis, and on the right side rather low down there was a mass which felt like a mass of enlarged glands. From time to time this mass could be felt in slightly different positions, the most constant being just to the right of, and below, the umbilicus. At first the child improved greatly, but at the end of July diarrhœa with some fever set in and he began to lose ground. The motions were pale, slimy, and drab-coloured. There was never any blood. In August and September he had several severe attacks of abdominal pain, which were accompanied by visible peristalsis, the small intestines being especially concerned. The diagnosis lay between enlarged tuberculous glands with matting together of coils of intestine and a chronic intussusception of the bowel. In the hope of relieving the obstruction laparotomy was performed by Mr. T. H. Kellock on Sept 28th. He felt some large glands and saw a few yellow tubercles on the peritoneum; some adherent coils of intestine were separated and a small band of fibrous tissue was divided. After the operation the child was completely relieved of the attacks of abdominal pain but his condition otherwise remained unaltered The diarrhœa recurred, he began to have an intermittent temperature, and gradually sank, and died on Oct. 12th

Necropsy.—The post-mortem examination was made 48 hours after death. In the head and thorax no abnormal condition was observed. On the parietal peritoneum in a few places there were small scattered granular tubercles but no general tuberculous peritonitis was present. On the right side the liver was bound to the abdominal wall by dense adhesions. The lowest part of its right lobe was involved in a mass which consisted of liver, intestine, peritoneum, and mesentery and they were so bound together that even careful dissection could scarcely separate the various parts. This mass lay to the right of, and rather below, the umbilicus, lying, in fact, over the lower half of the right kidney. On dissecting the mass the appendix was found lying in a line pointing vertically upwards behind the colon. Its tip, however, on the inner side of the colon was adherent to the lowest part of the right lobe of the liver; and matted round this point were loops of small intestine, the mesentery, the ascending colon, and several large glands, in one of which there was a caseous focus. In two places at least there was a fistulous communication between the appendix and the small intestine which was much ulcerated. The ascending colon showed very little ulceration and no fistula was found. On opening the loop of small intestine two small brownish bodies fell out which resembled the kernel of some fruit, such as an apricot. The small intestine above the portion involved in the tumour had its walls remarkably thickened and hypertrophied. The descending colon was the site of very numerous small ulcerations, some of which showed tubercles on the peritoneal surface, and all were transverse to the gut and had edges slightly raised and much undermined The lowest portion of the sigmoid flexure was caught up and fixed by strong adhesions to the tumour above. The spleen showed a few granular tubercles and one small caseous patch. The mesenteric glands were rather larger than normal and in one of these there was a *focus of caseation, but no mass of large glands was found.* The glands elsewhere were normal.

Remarks by Dr LEES.—An accurate diagnosis of this case may fairly be said to have been impossible. The mass felt on admission was thought to be composed of caseous glands and intestine matted together by a chronic tuberculous process. The history given by the mother seemed to be in accord with this view, the blood passed on two occasions per rectum and the diarrhœa being ascribed to tuberculous ulcerations of the bowel. The attacks of abdominal pain and the visible peristalsis were ascribed to the obstruction caused by the implication of the intestine in the mass which could be felt. But when the peristalsis became extreme, coils of small intestine pushing forward the abdominal wall in prominent ridges during the attacks of pain, it was determined to try whether any relief could be given by operation. The laparotomy revealed adherent intestine, enlarged glands, and some tubercle. As much separation of the adhesions was effected as seemed possible without incurring the risk of rupture of the bowel But the facts that a coil of small intestine was adherent to a diseased appendix vermiformis, with two communications into it, that the tip of the appendix was adherent to the liver, and that the adherent bowel contained two foreign bodies, were revealed only by the necropsy. It may be added that the foreign bodies were precisely similar to one another, being oval in shape and quite unlike the "fæcal concretions" which often perforate the appendix.

Remarks by Dr. THURSFIELD.—Pathologically the points of interest seem to me to be the unusual position of the appendix and the question of the sequence of events—that is, whether the tuberculous *infection* preceded and determined the formation of the adhesions between the liver and appendix or whether the tuberculous infection took place in a part of the intestine which was already the seat of inflammation. I do not think that it is possible to advance beyond speculation, but probability appears to me to point to the first solution The presence of the foreign bodies I regard as accidental and quite recent.

BEDFORD COUNTY HOSPITAL.

A CASE OF SUPPURATIVE APPENDICITIS WITH SECONDARY LIVER ABSCESSES.

(Under the care of Mr. W. GIFFORD NASH.)

ABSCESS of the liver occurring in the course of appendicitis is nearly always the result of a septic thrombosis or of a pylephlebitis, but, as in the case here recorded, it may be due to direct extension of the suppuration. Hepatic abscess was present in 11 out of 257 cases published by Fitz,[1] Hawkins met with one case in 38 cases of appendicitis,[2] and Mynter[3] saw one case in 75 cases. For the notes of the following case we are indebted to Mr. F. H. Allfrey, house surgeon.

[2] Mynter Appendicitis, p 89

[3] American Journal of the Medical Sciences, October, 1888.

A boy, aged 15 years, was admitted into the Bedford County Hospital on Sept. 27th, 1899, with abdominal pain and high temperature He had been in gaol for some weeks and on Sept 12th Mr. Nash had been called in because the patient had some diffuse abdominal pain. On the next day the pain was chiefly in the right iliac fossa and vomiting had occurred five times, but there was no rise of temperature. On the 14th there were tenderness and increased resistance in the right fossa; the temperature was normal, but during that night he shivered. On the next day the tenderness was very marked; the bowels were opened after a small dose of castor-oil. The morning temperature was 103° F. and the pulse was 108. On the 16th he was sick once; the temperature was 102° in morning and rose to 103° at night. For the next three days he seemed better, the temperature remained down, and the pain was less; except for some tenderness there was nothing to be felt in the right fossa, and the percussion note was resonant. On the 20th the patient sweated during the night and the temperature again rose to 101°; the bowels were not open; the tongue, which had been thickly coated, was cleaner. During the next four days the temperature rose to 102° at night; sweating was noticed at times; the bowels were open several times, the motions being loose on the 23rd. On the 25th increased resistance was felt over the ascending colon. While in gaol he was treated with small doses of calomel and with sodium salicylate and bismuth.

When admitted to the hospital on Sept. 27th the boy looked ill and complained of general abdominal pain. Nothing abnormal was found in the chest except that the liver dulness in the mid-axillary line began at the upper border of the seventh rib. The abdomen moved slightly all over; no prominence or fulness was to be seen. Slight tenderness was complained of on firm pressure in the right iliac fossa; the right half of the abdomen was slightly more resistant than the left. No tumour could be felt in the appendix region, but beneath the right costal margin was a firm swelling extending about two inches from the ribs; it felt like liver, but did not move on respiration. The abdomen was everywhere resonant except over this area in the right hypochondrium The tongue was thickly coated, the pulse was small and rapid, and the temperature was 103°. A simple enema was given with good result. On the 28th the temperature, which was 103° at 2 A.M., fell to 96° at 6 A.M. The patient passed a fairly good night but sweated freely.

On Sept 29th Mr. Nash operated. An incision was made from the right linea semilunaris about an inch above the crest of the ilium to the mid axillary line; at the hinder end of this wound pus was seen flowing from behind the colon. A cavity was opened up extending upwards and downwards, and a concretion of the size of a large pea was felt in and removed from the lower part of the abscess cavity behind the cæcum. The pus had a strong fæcal odour and contained fæcal matter On irrigating the cavity with 1 in 2000 perchloride of mercury solution a slough about four inches long came away, which proved to be the remains of the appendix. The cavity was plugged and the wound was left open. About an hour after the operation the temperature rose to 105° and the patient had a rigor lasting several minutes. For two days the temperature ranged from 98° to 104°, the sweats and rigors continued, and the pulse averaged 108 and respirations 26. Quinine was given every four hours On Oct. 2nd the patient became rapidly worse; the wound showed no sign of repair, being covered with a green slough, and there was no discharge from the abscess cavity; the respirations rose to 40 and the pulse to 140. He died the next morning, five days after operation and 21 days from the onset of the symptoms.

Necropsy.—Post mortem there was no sign of general peritonitis, but, extending upwards from the cæcum behind the colon was an abscess cavity between the layers of the mesocolon; the mesocolon at the hepatic flexure was adherent to the liver, and on separating these adhesions the under surface of the liver was found to be rough and ulcerated. A section through the portion of liver in the neighbourhood showed numerous abscess cavities, the largest having a diameter of about half an inch. The stump of the appendix, about an inch in length, was found lying curled upwards behind the ileum. About two inches above the ileo cæcal valve on the posterior surface of the colon was another perforation leading into the abscess cavity. There were three suppurating retro-peritoneal lymphatic glands.

Remarks by MR. ALLFREY.—The most noticeable fact about the case was the absence of physical signs, but this is accounted for by the course which the pus took behind the colon. An operation in gaol could not be easily managed, and even after the patient's admission into hospital there was some doubt as to where to operate in the absence of any swelling or dulness. It is possible that the temporary improvement after Sept 17th was due to the discharge of the pus into the colon through the second perforation. The abscesses in the liver were evidently due to direct infection from the original abscess cavity and not the result of infection by the portal system, for they were confined to the region of the impressio colica. It is quite possible that if an early operation had been performed the result would have been different, for the pus would then have been liberated before it had reached the liver.

Medical Societies.

PATHOLOGICAL SOCIETY OF LONDON.

Forms and Significance of Proteids in the Urine.

A MEETING of this society was held on March 20th, Mr. A. PEARCE GOULD, the acting President, being in the chair.

Dr. T. G. BRODIE resumed the debate on the Forms and Significance of the Proteids met with in the Urine. He fully endorsed Professor W. D. Halliburton's explanation of why serum albumin was usually more abundant than the globulin. It was largely a question of the relative size of the two molecules. When a simple proteid solution was filtered through ordinary filtering-paper the resulting solution became weaker and this weakening of the solution by filtration was more marked in the case of globulin than serum albumin. He then proceeded to describe some experiments which tended to explain the variations observed in the nature of the proteid present in cases of albuminuria. In the first place he instanced the evidence gained by filtration. All experiments tended to show that the albumin molecule was of smaller size than that of the globulin, that a filter having finer pores was necessary to hold back albumin molecules than one which completely prevented the passage of globulin. In the next place he described the results as to the artificial production of albuminuria when the excised kidneys of an animal were kept alive by perfusion of defibrinated blood through them. In these cases it was found that at first the urine was often proteid-free. In a short time, however, hæmoglobin made its appearance. Later—i.e., in about two hours' time—the urine contained a considerable quantity of proteid which was found to be chiefly serum albumin, only a very small quantity of globulin being present. In another series of experiments he used dead kidneys, injecting various hardening reagents (commencing with warm methylated spirit) to keep the renal tissues *in situ* and intact. Starting from these and similar points he argued that the usual variation in the nature of the proteid could to a great extent receive an explanation based upon the physical conditions of filtration present and the different size of the molecules of the various forms of proteid. Turning to the clinical aspect of the question he had found that in the renal disorder attending cardiac disease the proteids in the urine were pretty much in the same proportion as they existed in the blood. In large white kidney and the granular contracted kidney there was mostly very little globulin compared with the albumin in the urine.

Mr. P. J. CAMMIDGE (Leeds) read a paper entitled Some Observations on the Proteids Excreted in Albuminuria. After describing the method he had employed in separating the proteids from the urine, he exhibited charts of the excretion of total proteids, serum albumin and serum globulin, in eight cases of albuminuria. These included cases of acute and chronic Bright's disease, amyloid disease, albuminuria of pregnancy, and eclampsia. He then made some remarks on these cases and pointed out that, as a rule, the most marked variations in amount took place in the serum albumin, the serum globulin being more constant, but that when the serum globulin did show marked variations the case tended to be more severe. He had examined altogether 198 specimens of albuminous urine taken from 28 cases. It would not, he thought, be right to draw any general rules from these, but the facts certainly had some bearing on prognosis and tended to show in the first place that the amount of the albumin in any given specimen of urine alone was not a safe guide as to the severity of the case. The total proteids in the 24 hours was, however, a better guide; but he regarded the presence and the amount of serum globulin as the most important indication of the extent of the disease of the kidney itself. Marked rises and falls in the amount of globulin seemed to indicate the probable approach of a fatal issue.

---

[2] *On Diseases of the Vermiform Appendix*, p. 97.
[3] Appendicitis and its Surgical Treatment, p. 90.

Dr. F. G. **Hopkins** (Cambridge) said he would confine his remarks to a case of physiological albuminuria which he had observed in a man aged 21 years. This man habitually passed small quantities of albumin. The albuminuria was closely related to diet—i.e., it only occurred three or four hours after a meal. The amount was small, never exceeding from one and a half to two parts per 1000. The curious part of the case was that the proteid that was passed was not always the same. It was always some form of albumin, but on at least one occasion, when he was confined to a diet of bread and milk, the proteid when separated by coagulation was found to contain no loosely combined sulphur, as it did when he was on ordinary animal diet. The patient was preparing for an examination and he (Dr. Hopkins) did not like to try the effects of different dietaries; but the facts elicited seemed to show how important it was in such cases to examine carefully the nature and quality of the proteid substance excreted. Such cases induced him to turn his attention to the intestines and the processes going on there. The intestines had to deal with, to disintegrate, and to build up by a process of synthesis, many different kinds of proteids from many different kinds of materials taken into the body in the form of food. He thought that much could be learned from an attentive study of cases of physiological albuminuria.

Dr. W. **Lee Dickinson** wished to confine his remarks to the clinical aspect of the question which he admitted was less precise than the laboratory results. His remarks would refer chiefly to the peptones or albumoses, and particularly that form known as hetero-albuminose, by which he wished to indicate a collection of bodies, amongst them Bence Jones's albumin, very like to each other, their common feature being coagulation at a low heat and re-solution at a higher one. The presence of these substances in the urine was not only associated with diseased bones, but had also been found with glycosuria, with myxœdema (by an American physician), and with leucocythæmia (of which he had met with one case). This kind of albuminosuria was always followed by death in the course of a few months. More ordinary kinds of albuminosuria or peptonuria had been described in connexion with measles, scarlet fever, typhoid fever, scurvy, the puerperal state, rheumatism, and cerebro-spinal meningitis. This change in the urine was also found in cases marked by suppuration or extensive inflammatory exudation, especially pneumonia and empyema. In observations made some years ago, among the class of cases usually found in the wards of a general hospital, he had found it limited to these two last-named diseases, and especially in severe cases a few days after inception, when the amount of peptone might be very large, in some cases reaching as high as 1 per cent. A rough examination might fail to find it in other cases. The best test was the cold nitric acid and biuret test, which required considerable care in the proportion of the reagents. Peptonuria was not an infallible evidence of suppuration; it had also been met with in fibrinous pleurisy and in purulent bronchitis. It only indicated extensive and severe inflammation with the formation of proteolytic products. It also indicated excretive activity in the kidneys. It was less frequent, he believed, than formerly. It seemed to be absent from abdominal inflammations, with the exception of an abscess bursting into the peritoneal cavity.

Dr. **Archibald E. Garrod** referred to certain circumstances attending paroxysmal hæmoglobinuria. Formerly this process was looked upon as the turning out of a foreign proteid, but from Dr. Brodie's observations it followed that the kidneys were not able to keep back hæmoglobin, or only in very small quantity. As regards what might be termed "foreign" albumins they seemed to be thrown out very readily. Egg albumin, for instance, if taken raw in very large quantities appeared in the urine, and he referred to a case in point. In reference to the general question of albuminuria perhaps in some cases the proteid itself was at fault, the albuminuria being due to a kind of "chemical malformation" in the individual.

Dr. F. **Parkes Weber** alluded to the frequent obvious presence in clear urines (generally of extremely low specific gravity) of what he believed to be a trace of mucin (nucleo-albumin). He likewise referred to the occasional presence of a substance which he supposed was a "bile mucin" in the urines of very grave and chronic cases of icterus (due to malignant disease or chronic obstruction of the bile-duct from cholelithiasis).

Professor W. D. **Halliburton**, in summing up the discussion, congratulated the society on the wide range and value of the contribution. He especially referred to Dr. Brodie's experiments. It was these which lent greatest support to the hypothesis he had advanced concerning the size of molecules and the permeability of cells as explaining the different forms of albuminuria. He thought Dr. Brodie's experiment of making a dead kidney in a bottle pass water added great confirmation to the physical as against the vital explanation. Mr. Cammidge's observations were interesting, but were open to numerous fallacies both in regard to the presence of pus and albuminose and also to certain fallacies in the processes employed. They only showed that serum albumin came through more readily than did globulin. Turning again, in conclusion, to the size of the molecules it was clear that some of the ordinary proteids possessed molecules of immense size, since hæmoglobin which was most easily diffused, possessed a molecular weight of over 1600.

OPHTHALMOLOGICAL SOCIETY.

Family Tendency to Ophthalmoplegia Externa.—Meningitis followed by Panophthalmitis.—Pigmented Tumour of the Eyeball removed; death from Multiple Pigmented Carcinoma nearly 14 years later.—Green Vision.—Exhibition of Cases and Card Specimens.

An ordinary meeting of this society was held on March 8th, Mr. **G. Anderson Critchett**, the President, being in the chair.

Mr. W. M. **Beaumont** (Bath) read details of a series of 12 cases of Ophthalmoplegia Externa occurring in Four Generations of an otherwise Healthy Family. This was no doubt due to nuclear disease limited to a small area. It was never congenital, but came on in adult life and slowly progressed until all the external ocular muscles were affected. Ptosis occurred in all and was an early symptom, but there was never ophthalmoplegia interna. In the advanced cases there was great weakness of the orbicularis palpebrarum. There was no other paralysis nor were any of the special senses affected. The first case—the ancestress of the family—died in extreme old age, her son died aged 90 years, while another died at the age of 85 years. One of the family had been shown to the society by Mr. J. B. Lawford and the case was recorded in Vol. VII. of the Transactions. Photographs of most of the others were shown and they all had ptosis. Mr. Beaumont thought that this was the first time that a family of 12 had been recorded suffering from this condition and he regretted that time and space—time because the cases were spread over four generations and space because they were spread over four quarters of the globe—prevented him from giving fuller details.—Mr. **Richardson Cross** (Bristol), who had seen one of the affected members, said the hereditary tendency was well marked and he had made a diagram of the relationships at the time. All the external eye muscles were affected.

Mr. A. **Quarry Silcock** read a paper on Meningitis followed by Panophthalmitis. He said that the interest in this case lay chiefly in the fact that both eyes were affected by a diffuse inflammatory change (panophthalmitis) the result of general septicæmia, and in so early a stage of the latter as to constitute one of its most prominent signs. The man, aged 35 years, was admitted to St. Mary's Hospital under the care of Dr. W. B. Cheadle on Oct. 14th, 1899. He was well and at work until Oct. 4th, when he was taken with shivering fits, pains in the chest, headache, cough with blood-stained sputum, and delirium at night. Since Oct. 7th he had persistent pain in the back of the neck. He answered questions intelligently; he complained of headache and pain in the chest. The temperature was 101° F. There were no symptoms of cardiac lesion or any obvious lung changes affording an explanation of the patient's condition. On the 15th, the day after admission, it was noticed that the right eye was inflamed (uveitis and hypopyon, chemosis of the conjunctiva). In the left eye the media were turbid, impeding a view of the fundus. The right eye was proptosed. On the 16th Mr. Silcock, after consultation with Dr. Cheadle, excised the eye, hoping that its examination would throw some light on the nature of the infection. This was done by Mr. H. G. Plimmer, who found that the infection of the eye was due to the streptococcus lanceolatus. The man became rapidly worse and died in a semi comatose condition on the 17th. The post-mortem examination showed extensive basic meningitis and subarachnoid hæmorrhage in the lower dorsal and lumbar regions; there were recent vegetations on the aortic valves and embolic lesions in the lung and the spleen. The proptosis of the right eye was clearly due to œdema of the orbit. The examination of the eyes (the left was examined by Mr. C. D. Marshall) showed purulent panophthalmitis, but whether this condition was secondary to meningitis or was a part of the septicæmic condition was uncertain.—The PRESIDENT remarked on the extreme rarity of the case and said that he had never seen one in which both eyes had been affected.—Mr. RICHARDSON CROSS said that though he had never seen a case in which both eyes were affected he had one case under his care in which one eye was lost during an attack of epidemic cerebro-spinal meningitis, and he read notes of this case.—Mr. NETTLESHIP said he had seen cases like that recorded by Mr. Cross. In one, a girl aged 10 years, attacked with a sister with symptoms attributed to influenza but closely resembling meningitis, there were iridocyclitis and lymph in the anterior chamber. Vision was recovered to the extent of [illegible]. In another case recorded in Vol. V. of the Transactions a child aged two and a half years had iridocyclitis in one eye with pains in the limbs and joints and the vitreous became opaque and degenerated. There was meningitis and death occurred after six weeks. Such cases had been called pseudo-glioma. Coagulated lymph was smeared over the iris and the eye usually become soft and shrunken.—Mr. E. TREACHER COLLINS had met with a similar case exhibiting iridocyclitis with yellow exudation into the vitreous. The eye was excised and the patient died with meningitis and otitis. The inflammation could be traced by way of the optic tracts and nerves to the papilla and eye.—Mr. HOLMES SPICER mentioned one instance in a woman aged 40 years in whom nodular iritis followed by shrinking of the globe occurred in one eye after the other in the course of a week, with loss of both, as a result of infective embolism derived from septic abortion.

Mr. HERBERT FISHER and Dr. CHARLES R. BOX related a case of Primary Pigmented Tumour of the Eyeball for which the eye was excised in 1885, the patient being a man at that time aged 42 years. 14 years later he was re admitted into St. Thomas's Hospital with great enlargement of the liver, accompanied by jaundice, abdominal pain, sickness, and diarrhœa, and œdema of the lower extremities. For 15 months the abdominal swelling had been progressing with general weakness and loss of flesh. The patient died and a post-mortem examination showed that the liver was almost replaced by a nodular mass of melanotic growth weighing 12 pounds 6 ounces. There were also a few pigmented growths in the left parietal pleura. A small pigmented growth of the size of a pea sprang from the myocardium and projected into the right ventricle. Microscopic examination of the liver growths proved *them to be melanotic carcinoma* and not sarcoma as had been expected. The eye containing the growth had been preserved and Mr. Trencher Collins was able to obtain sections of it. He reported the growth to have originated in the ciliary processes and to have extended thence into the iris and through the sclerotic. The cells were pigmented to a varying degree; they were small, polygonal and of an epithelial type and from their arrangement in rows Mr Collins gave it as his opinion that this growth was carcinomatous in character. It was decided to submit the sections to a pathological committee of the society for further examination and report.—The PRESIDENT remarked on the extreme rarity of the case.—Mr. COLLINS supported his view as to the origin and nature of the primary growth.—Mr. DEVEREUX MARSHALL, although expressing no opinion as to the nature of the primary growth, said he had never heard of a case in which a true cancer had remained dormant for 14 years, though he had seen and published a case in which a patient had died from metastatic sarcoma 11 years and five months after an eye had been removed for sarcoma.—Dr. BOX added some details of the case, and Mr. H. FISHER briefly replied.

Mr. H. WORK DODD said that some months ago he exhibited to the society a patient who saw everything green, and since that time he had collected 13 published cases of this condition. In reviewing these he came to the conclusion that neither sex nor age had to be specially considered, and that errors of refraction and their effects might be excluded. The condition of the general health was noticeable in seven of the cases; two suffered from migraine, two from syphilis, and three from chronic lead poisoning. 10 of the cases showed some departure from the normal in their ocular structures, such as wounds, detachments of retina, choroiditis, optic atrophy, neuro-retinitis, as well as tortuosity of the retinal vessels. With the exception of two cases following one a wound and the other an operation for cataract the abnormalities were connected with the optic nerve and retina. As to the reason why these people had green vision these cases gave but little information. It should, however, be noted that the macular region of the retina in three of the cases was the part affected, and in two of the others the temporal side was indicated as being particularly disturbed. Looked at in the light of our knowledge of the conditions existing in tobacco amblyopia, possibly the same tissues were affected in the two conditions. Two of the cases in which green vision was noted only when the patients were in-doors seemed to depend on the character or degree of the illumination.

The following cases and card specimens were shown:—

Mr. J. B. LAWFORD: Growth (? tuberculous) in the Macular Region.

Mr. E. TREACHER COLLINS: Unusual Changes in the Macular Region.

Dr. N. BISHOP HARMAN: Central Choroiditis.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

The Effect of Heredity on Disease.

A MEETING of this society was held on March 7th, Mr. A. G. MILLER, the President, being in the chair.

Professor D. J HAMILTON of Aberdeen read a paper on the Effect of Heredity on Disease. He drew attention in the first place to the enormous amount of literature which had arisen on both the biological and medical aspects of the question. The mere congenital transmission of a disease from parent to child was not heredity. Most of such alleged cases were merely the result of contagion applied to the fœtus—the direct inoculation of the fœtus through the blood of the mother. Two theories had received *most acceptance as regards heredity*: (1) the pangenic theory *of Darwin*, or the transmission of acquired features; and (2) the theory of Weissmann, or the continuity of the germ plasm. With reference to what were generally known as hereditary *diseases*—e g., *tuberculosis*—it was undeniable that that disease affected members of the same family and that the tendency to it had persisted in preceding generations, yet it was now asserted that the disease was not hereditary in young animals. The tendency depended either on direct inoculation or in the inheritance of a tuberculous predisposition to the disease. These could not, however, be the only causes. The conformation of the body showed it, as did also the liability of such individuals to certain other diseases. It was the habit of body which was inherited. Professor Hamilton thought that the epithelial coverings of the body in such individuals were too easily penetrated—that they did not resist the attacks of the tubercle bacilli sufficiently. It had been shown that when tuberculosis had been introduced amongst savage nations they had been decimated. No member of any community was immune to tuberculosis and there were few who could not be inoculated successfully. The lungs were the organs of the body which were chiefly affected and the epithelial coverings of these organs were very thin and delicate. Amongst children who exhibited the tuberculous form of body it was found that catarrhal pneumonia and attacks of bronchitis were frequent and this might be due to an abnormal penetrability of the epithelium. It was not yet known whether the epithelium in other parts of the body in those predisposed to tuberculosis was preternaturally vulnerable. The great point to note was the great vulnerability of the epithelium and this was handed down from generation to generation. The dark olive appearance of the skin, the colour of the hair, the length of the eyelashes, the lanugo-like hair along the course of the spine and on the legs, all pointed to an abnormal condition of the epithelium, and this might be a cause for the predisposition. How had this habit of body arisen? Could it be generated by vicious surroundings or would such agencies produce such a condition? Professor Hamilton thought not. They must go much further back. These tuberculous features were due to a variation which had taken place far back in their history and which had been propagated. It might have been confined to one race at first, and so that certain type of constitution might have arisen. Gout was said to be engendered by high living and to be transmitted. It might, however, skip a generation and re-appear in the succeeding one. In many people no amount of food or drink would excite gout. Were the complex phenomena really due to high living? Might they not be a reversion to an earlier type? For example, birds and reptiles normally excreted large amounts of uric acid. The gouty habit had arisen as a variation and so was transmissible. Mental diseases, neuroses, &c., all showed a vulnerability of the nervous system and it was possible that this might be related to the vulnerability of the epithelium. Nerve cells being so highly complex easily underwent degeneration. Such cells might break down as a result of strain due to an acquired lessening of resistance. Could external agencies bring about changes in the nerve-cells and might these be transmitted? Professor Hamilton referred to Brown-Séquard's experiments on guinea-pigs and the transmission of the epilepsy so produced to the offspring. Was there absolute proof to show that nervous diseases could be produced by, e g, alcohol, and could these be transmitted? He thought that they had not this proof. In such nervous diseases there was probably an acquired weakness which was excited by some stimulus. Syphilis was not hereditary, but it certainly was congenital. It tended to die out in the early life of the first descendant. Hæmophilia was often truly a hereditary disease. It was a disease of the blood-vessels and not of the blood. This peculiarity was transmitted, as was also the tendency to hæmorrhoids. In hæmophilia, however, Professor Hamilton thought something more was transmitted and that it might be related to menstruation. The disease usually affected males and so it might be allied to the condition of fever, congestion of the genital organs, &c, which was seen occasionally in men at intervals of about a month (male menstruation). Might not hæmophilia be a manifestation of this menstruation in the male? Was there any evidence of the hereditary tendency to disease becoming eradicated by the breeding of certain strains liable to certain diseases with other strains having no such tendency to those diseases? As regarded variation in constitution, if a vicious line were introduced it might die out by breeding with pure stocks As a cause of malformations in the fœtus Professor Hamilton believed that so-called maternal impressions had no effect. There was no evidence to show that a diseased first father might so influence the mother that the children of a second father might be affected. There was no evidence proving that a diseased condition of the body excited by external agencies could be transmitted.

Dr. T. S. Clouston said that Weissmann in his work on heredity made three striking admissions: (1) he admitted that the germ cells could be infected as by syphilis and so a disease might be transmitted; (2) that the law of non-transmission of effects of external agencies did not apply to the lowest organisms—that when they went low enough external agencies did act; and (3) that environment, especially climatic environment, had an effect on the nutrition of the germ cell so that it might be altered and thus the fœtus might be different from the parent. These admissions went a long way to satisfy the widespread medical opinion that heredity existed, as seen, for example, in five or six generations of tuberculous families. Again, the psychopathic constitution all its varieties might be studied for generations. Through environment and evil climatic and dietetic conditions the germ cell might be affected. What could a good heredity give to an individual? A normal development was the greatest power given to an organism. If they had a debasement they got the origin of a vast number of the neuroses. By far the largest number of the neuroses developed during the developmental stage—e g., epilepsy and St. Vitus's dance. Congenital defects likewise showed themselves at this period. Insanity occurred in its most marked forms in the developmental stages. When they thought of the immense complexity of each brain-cell they had only to realise that a very slight debasement of the developmental process would cause many of these lesions. Hereditary defects were due to an arrest of the maturation of the nerve-cells and these might give rise to many of the neuroses. The sexual and reproductive instincts threw an enormous strain on the constitutions of young men and girls. Growing old and dying were normal processes, but many became insane owing to an unphysiological mode of growing old. One set of tissues grew old in advance of others. In certain families there ran a tendency to an excessive use of alcohol. Many people had a lack of higher mental inhibition. The worst class of dipsomaniacs were adolescent cases. The disease arose during development. It was not a craving for alcohol but the controlling power was quite deficient. It was a hereditary weakness in reacting to alcohol and a very small amount had an intense effect upon them.

Professor Cossar Ewart congratulated Professor Hamilton on the orthodoxy of his teaching from the point of view of the biologist. He stated that variation was enormously common now; there were even epidemics of it. If they mixed up two different strains of wild animals they got a variation. Amongst the human race there was a constant mixing up and so there was a constant production of variations, and thus tuberculosis, gout, &c, might arise at any time. As regarded the influence of environment on germ-cells Professor Ewart stated that his experiments showed that the germ-cell was excessively sensitive but that they did not show that there was any transmission of acquired characters Examples were cited to show that the maturity of the egg determined the condition of the adult. Professor Ewart believed that reversion did exist.

Dr. J. W. Ballantyne said that he had never believed in the theory of maternal impressions There was evidence to show that fœtal tuberculosis did exist and that congenital cardiac disease might be due to tuberculosis in the mother. Malformations were more frequent in the descendants of those who had been alcoholic, gouty, rheumatic, or insane. The ultimate solution of the question of heredity must be arrived at through the germ

Professor Stewart Stockman, after some preliminary remarks, said that in all probability what was called the "tendency" to tuberculosis in human beings was the real disease and that if treated by tuberculin they would react. In the slaughter-houses of Edinburgh about 6000 calves were killed yearly and only one showed evidences of congenital tuberculosis. Of cows, from 12 to 80 per cent. were tuberculous Of bullocks slaughtered not 1 per cent were found to be tuberculous Tubercle bacillus from one species often failed to produce the disease in another, as, for example, fowls seldom took human tuberculosis. Cancer was never thought by veterinary surgeons to be hereditary in animals; and glanders, though it ran a very chronic course, like tuberculosis, was not hereditary.

Dr Alexander James, Mr. Joseph Bell, and Professor Schafer took part in the discussion and Professor Hamilton replied.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of State Medicine.

Presidential Address.—Infantile Insanity.

A meeting of this section was held on Feb. 16th.

Sir Charles A Cameron, C B., on taking the Presidential chair, thanked the Council of the Section for having nominated him as President and the Academy for having elected him. He then gave a short historical account of the origin of the section. The Academy was formed in 1882 by the amalgamation of the Medical, Surgical, Pathological, and Obstetrical Societies. At that time there was in existence a Society of Metropolitan Officers of Health, which met monthly and of which he was President. He suggested that as the various medical societies were being amalgamated it would be desirable that their society should enter into the union under the title of the Section of Hygiene. There was considerable opposition to this proposal on the grounds that it would unduly increase the number of sections, but ultimately the proposal was adopted in a modified form and a sub-section of hygiene was constituted. The four sections were each to have a president, but the sub section was to have only a chairman. Some years subsequently the sub-section was elevated to the dignity of a section and the chairman was converted into a president. He was the first chairman, and now, after an interval of 18 years, he again filled the highest office under the title of president. While commenting on the notification of infectious diseases he said that the Corporation of Dublin had included measles and whooping-cough in the schedule, but whooping-cough had since been eliminated, as no good had resulted from notification of that disease. Measles was hardly notified in any town save Dublin, but it was desirable that it should be notified. With regard to the use of preservatives in food he believed that some of them, such as boric acid, if used in moderation, would be useful. It was better to consume food kept fresh with a very moderate amount of preservative rather than food in a state of incipient decomposition and containing deadly ptomaines.

Mr. WALTER BERNARD delivered an address on Infantile Insanity. He said that the importance of studying the science and art of influence in the peculiarly impressionable epoch of infant life, during the many-sided, rapid periods of evolution, had hitherto been practically disregarded. Here it was not to the specialist that aid and the solving of difficulties must be looked for. The family practitioner alone was placed in the position for disciplining the faculties by his observed facts, and while engaged in this work for the future culture of the world he elevated those who carried out his directions on mental sanitation, practical life, knowledge, and truth. Besides, he held the key to the family pedigree and ancestral history. His insight, extended experience, and close observation enabled him, at this very early stage, before mental action and mentation were evolved, to control inherited conditions. By judicious training those born with insane propensities could be made not only able to take care of themselves, but could be converted into good citizens.

Dr. DOYLE thought that self-control was the point needing greatest emphasis. He had seen very marked improvement effected in a case which had been sent to an institution in Holland where the patients were taken charge of by farmers and where no education was attempted, the patients being chiefly employed in manual labour.

Sir FRANCIS CRUISE said that he had seen children of two and three years of age whose mental condition pointed to insanity and who ultimately proved to be insane. He was strongly convinced that a great many children were insane.

Dr. LITTLE agreed that a great deal could be done in the training of children who had a tendency to grow up imbeciles, About 15 years ago a boy came under his notice who was growing up an imbecile He was sent to an institution near London and he was now in a good position.

The PRESIDENT referred to the work which was being done by the London School Board in the training of children with impaired intellects. The children were examined by the medical officers of the Board and special classes had been formed for the purpose of teaching those who were the subjects of mental disease.

OTOLOGICAL SOCIETY OF THE UNITED KINGDOM.—A meeting of this society was held on March 5th, Sir William Dalby, the President, being in the chair.—The President announced that the council had appointed an investigating committee, consisting of himself, Dr. Herbert Tilley, and Mr. Arthur Cheatle, to inquire into the Condition of the Ears in School-children —Dr Dundas Grant showed a case of old-standing Perforation in the Postero-Superior Segment which had been healed by means of the application of trichloracetic acid and in which there was improvement in hearing.—Dr. Urban Pritchard showed a patient who had had the Malleus Removed for long-standing Suppuration with Perforation in the Membrana Flaccida. Sound healing had occurred and the hearing was improved.—In discussing the case Mr. Richard Lake and Mr. Cheatle advocated the operation of removing the remains of the membrane and ossicles in cases of chronic suppuration in which healing did not occur as a result of thorough ordinary treatment and in which there was no indication for the complete post-aural operation. If the operation failed to cure it served demonstrate that more radical measures were necessary.—Mr. C. A. Ballance had seen a good many of Mr. Lake's cases and had been highly pleased with the results.—Mr. Richard Lake showed a patient who had an Exostosis growing from the Posterior Wall of the Right Meatus and almost filling the canal which was periodically blocked by cerumen.—The President and Mr. Cheatle advised chiselling the growth away after turning the auricle forwards —Mr. Lake also showed a patient with Destruction of both External Attic Walls resulting from chronic suppurative trouble in that region. The disease was soundly healed and the remainder of the membranes was intact.—Dr. Herbert Tilley showed a child with Congenital Dimples in Front of each Auricle. The condition was present in the father, in three of the aunts, in an uncle, and in a cousin.—Mr. Arthur Cheatle related a case under his care in which a Dimple was present on one side and a Sinus on the other. The sinus extended upwards, backwards, and inwards for some distance; an abscess formed periodically, leaving an ulcer which would heal, but the sinus remained. Healing occurred after laying the various branches freely open, dissecting away lining membrane, and applying pure carbolic acid —Dr. William Milligan had seen a similar case which was tuberculous.—Mr. Cheatle also showed two patients on whom the Complete Post-aural Operation had been performed, in the first case five weeks previously and in the second case three weeks previously. Packing had been left off in both, and they were being treated by daily syringing with carbolic lotion, 1 in 60, and instillation of spirit, nitrate of silver being applied to any exuberant granulations. There was little discharge in either case —Mr. Ballance recommended epithelial grafting and stated that the bone surface could thereby be completely healed within a fortnight of the original operation, possibly in less.—Dr. Milligan and the President concurred.—In reply to Mr. E. B. Waggett, Mr. Ballance said he had used small grafts, but they were not at all comparable in results with the large grafting method.—Mr Arthur Cheatle showed specimens from Fœtal to Adult Life of the Recess under the Fallopian Aqueduct. The space had been described by Steinbrugge and named by him "sinus tympani." Mr. Cheatle also described a recess outside the eminentia pyramidalis which sometimes ran outside the Fallopian aqueduct and dipped downwards for some distance —Mr. W. C. Bull showed a Sequestrum of the Petrous Bone which had been exfoliated spontaneously from a child, aged three years, leaving a smooth healed cavity.—Mr. Ballance suggested that it was tuberculous in origin.—Mr. L. A. Lawrence showed an elderly woman with a Papillomatous Growth in the Meatus. The opinion was expressed that it was probably malignant and that radical operative measures were necessary.—Dr. StClair Thomson showed a man with a Perforation in Shrapnell's Membrane with Cholesteatomatous Formation.—Cholesteatoma was also packed down behind the posterior segment.—Mr. Ballance and Mr. Cheatle advocated removal of the membrane, the malleus, the incus, and the outer attic wall, and if these measures were not successful the complete post-aural operation. In discussing the cases shown by Dr. Dundas Grant and Mr. Arthur Cheatle at the last meeting of Recovery from Thrombo-Phlebitis of the Lateral Sinus following clearing out of the Sinus without Ligature of the Internal Jugular Vein, Mr. Ballance thought that if a localised abscess was present in the sinus it was not necessary to ligature the vein.—Dr. Milligan alluded to a similar case described by Mr. A. Young in the *Glasgow Medical Journal* —With regard to Mr. Cheatle's case of Adeno-Carcinoma of the Meatus the President said it was rare for malignant disease to attack the meatus in that way. All the cases he had seen of epithelioma commenced in the tympanic cavity with the exception of one, which commenced in the skin over the mastoid process —Mr. A. E Cumberbatch related a case of Malignant Warty Growths of the Meatus in a woman aged 64 years —Dr. Milligan and Mr. Secker Walker related cases of Epithelioma of the Auricle.—Mr. Cheatle stated that cancer was much more frequent on the auricle than in the meatus, as many specimens of the former were found in the museums of the London hospitals and exhibited in the International Congress Museum, while of the latter the number was very small.—In discussing Mr. Waggett's case of Exfoliation of the Cochlea the President and Mr. Lake alluded to similar cases.—Mr.

Ballance said that as there was still suppuration from the petrous portion further operation was necessary in view of the danger of possible infection of neighbouring parts. He had healed cases of suppuration in the same situation.

British Gynæcological Society.—A meeting of this society was held on March 8th, Dr. W. J. Smyly, the President, being in the chair.—Mr. E. Stanmore Bishop (Manchester) showed the following:—(1) Sclero-cystic Ovary, History and Symptoms simulating Ectopic Pregnancy; (2) Double Papilloma of the Broad Ligament; (3) Large Pyosalpinx, the symptoms of which simulated Appendicitis; (4) Sloughing Fibro-myoma; and (5) Multiple Uterine Fibro-myoma, with central suppuration in one mass.—The discussion on these specimens resolved itself mainly into a discussion of Mr. Stanmore Bishop's final proposition—namely, that whilst some fibroids such as those discovered by accident having given rise to no symptoms whatever are best ignored entirely, whenever a fibro-myoma shows signs of growth it is wisest to remove it, and with it the organ in which it has developed, the uterus; the removal or otherwise of the appendages to depend entirely on their diseased or healthy condition.—After some remarks by Dr. Mansell Moullin and Dr. C. H. F. Routh Dr. Macnaughton Jones said that it had been laid down as an axiom in surgery that if the risks attendant upon an operation were not in themselves greater than those arising out of the disease for which it was proposed to operate, then operation was advisable and justifiable. The mortality from fibroids which were left alone was probably at least equal to 8 per cent., which was the percentage of fatal results from supra-vaginal hysterectomy in skilled hands. Of course, there were tumours which gave rise to no troublesome symptoms and which no one would operate upon and in which operation would not be justifiable.—Mr. Bowreman Jessett expressed his surprise at the paper recently published by Dr. F. H. Champneys in The Lancet[1] giving the mortality of hysterectomy for fibroids at 18 per cent. It was to be remembered, as had been pointed out by Mr. Harrison Cripps, that many of the patients who were operated on in St. Bartholomew's Hospital were already *in extremis* before operation; such cases should not be included when estimating the mortality of the operation; they, however, amply supported Mr. Stanmore Bishop's contention that cases which gave rise to symptoms should be operated on early.—After some observations by Dr. Herbert Snow and Mr. Charles Ryall, Mr. Christopher Martin (Birmingham) remarked that the question of the early removal of fibroids turned very largely on the risk of malignant changes supervening in these tumours. As to the choice of operation, he preferred panhysterectomy, of which the results were very good; he had now done 35 of these operations with one death.—Dr. William Walter (Manchester) advocated the *via media;* further they had to be influenced by the position of the patient. If she were a working woman, whose family depended on her work for their maintenance, operation should not be insisted upon unless the tumour were altering in consistence or increasing in size.—Dr. T. M. Dolan (Halifax) said that the difficulty experienced by general practitioners in the matter resulted from the fact that such wide divergence of views obtained among the leaders of the profession. He deprecated the attitude of those who advocated that the patient should wait for the "change of life"; by the time that this came about the patient was in many cases moribund and all that was left for the general practitioner to do was to sign the death certificate.—Dr. Inglis Parsons pointed out that among working women an operation was often urgently required in order to enable them to do the work on which their very existence depended; but it was often permissible to do no operation in the case of a patient who could afford to be an invalid.—The President expressed his belief that the mortality of the operation depended not only on the dexterity, but also on the views, of the operator: one who believed that most cases should be operated upon would probably have a mortality of from 5 to 8 per cent.; one who held the views of Dr. Champneys would probably reach a mortality of from 18 to 20 per cent.; whilst the surgeon who held an intermediate position would have an intermediate mortality. He congratulated Mr. Christopher Martin on his excellent results and expressed his own preference for the operation of panhysterectomy.—Mr. Stanmore Bishop replied.—Dr. Macnaughton Jones exhibited the Right Appendages of a patient in whom there had been a complication of symptoms—renal, uterine, and peritoneal—making the diagnosis of the actual condition difficult. She suffered from endometritis and had been recently married. Operation by posterior colpotomy revealed a cyst in the right mesosalpinx lying upwards and to the left side, while the ovary, enlarged and cystic, was in the normal position. The cyst was tapped and the adnexa were removed. The patient was now well. Dr. Macnaughton Jones also showed a large solid tumour of the ovary complicating cystoma. The solid mass filled the entire pelvic cavity. A diagnosis had been made of fibroma of the uterus, but laparotomy proved that it was ovarian. A report on the nature of the tumour would be made by Mr. J. H. Targett. The patient was doing well. He showed also a large Fibroma of the Uterus removed by Supra-vaginal Hysterectomy from a patient who had been several times operated on for sarcoma of the breast, with recurrences in the side of the thorax. From this she had perfectly recovered and it was feared that the pelvic tumour was also sarcomatous, but it proved to be a fibro-myoma. The patient made a good recovery.—Dr. William Walter showed a specimen of Uterine Myoma complicating Pregnancy.—Mr. Skene Keith showed a recent specimen of a large Uterine Myoma weighing 36 lb. The patient was progressing favourably.

Liverpool Medical Institution.—The fourth meeting of the Pathological and Microscopical Section of this society was held on March 15th, Mr. F. T. Paul being in the chair.—Mr. F. W. Bailey showed specimens of a Carneous Mole and of a Nasal Polypus expelled by sneezing.—Dr. J. Lloyd Roberts showed an Aortic Aneurysm from a man who had been under observation for a long time and who died from other causes. During expiration the pulse in the right radial artery disappeared and it was suggested by Dr. Hay that as the aneurysm was on the posterior region of the aortic arch it was pressed during expiration against the innominate artery and so caused the right radial pulse to disappear.—Dr. J. Wiglesworth showed a case of Double Porencephaly.—Dr. A. W. Campbell showed specimens and drawings illustrating the arrangement of the nerve-cells and nerve-fibres in the cerebral cortex in cases of idiocy. The drawings, which were of special excellence, were made to scale with the aid of an Abbé's drawing apparatus.—Dr. Alexander showed specimens of a Round-celled Sarcoma of the Testicle and Tunica Vaginalis of nearly three years' growth.—Dr. K. A. Grossmann showed specimens from a Tumour of the Orbit of six years' growth. Partial removal in 1894 resulted in recovery of sight; in October, 1899, it was found necessary to remove the new growth and the eyeball. The growth consisted of spindle cells, fibrous tissue, and muscle fibres.—Mr. Larkin showed specimens from an Epithelioma of the Penis. The growth was accompanied by extreme pain, and Mr. Larkin drew attention to the fact that it had extended along the perineural sheaths of the nerves, separating the lamina and causing proliferation of its cells, and that this would account for the pain. Mr. Larkin also showed a specimen of Multiple Carcinoma of the Scalp. Between 20 and 30 small tumours were present, varying in size from that of a small pea to that of a hazel nut. They were all quite separate. The occipital glands were secondarily affected. The structure resembled rodent ulcer.—Professor Sherrington showed normal specimens of the Organ of Corti and sections of the Brain from the Olfactory Region of the Rabbit.—Dr. R. J. M. Buchanan showed a specimen of a Nipple from a case of Early Cancer of the Breast. The nipple was clinically healthy, but the microscopic examination proved it to be profusely infiltrated with cancer.—Dr. Bradshaw showed specimens of a rare Crystalline Urinary Deposit.—The specimens were discussed by Mr. Paul, Dr. Alexander, Dr. Hay, Dr. J. Lloyd Roberts, Mr. O. Bowen, Dr. Grossmann, and Mr. Larkin.—Dr. Hay read a note on a Series of Hearts containing Thrombi. The thrombi were old-standing and not of the cadaveric or "agony" type. The series served to illustrate (1) the usual sites of thrombi; (2) the forms of thrombi; and (3) the associated conditions, and they included thrombi in the left auricle, left auriculo ventricular orifice obstructing the blood flow, in the apex of the left ventricle, in the infundibulum of the left ventricle giving rise to signs of aortic obstruction, and attached to the aortic valves.—In the series there were solid, dense thrombi, cystic thrombi, stratified flat thrombi, and pedunculated thrombi. The note was illustrated by specimens, photographs, and lantern slides.—*Dr. J. Barr discussed the note and Dr. Hay replied.*—Mr. F. T. Paul read a short paper on Congenital Cysts of the Neck. Attention was specially drawn to cysts arising from the sinus præcervicalis, the thyro glossal duct, and lymph angiomata. Mr. Paul considered that owing to the dual character of the structure of the cysts arising from the second branchial cleft the cysts were derived partly from the surface and partly from pharyngeal structures, the latter containing much adenoid tissue in the form of small nodules. Cysts from the thyro-glossal duct were lined with columnar ciliated epithelium and were situated in the median line.—In the discussion which followed Mr. Larkin recognised in the cysts from the second branchial cleft structure resembling the tonsil.—Professor Sherrington stated that in 30 thyroid glands from dogs examined by him he only remembered one having ciliated epithelium.—Mr. Paul replied.

---

[1] The Lancet, Jan. 20th, 1900, p. 147.

British Laryngological, Rhinological and Otological Association.—A meeting of this society was held on March 9th, Dr. Barclay Baron, the President, being in the chair.—The President alluded with regret to the loss sustained by the association in the death of Dr. MacNeill Whistler, one of its founders and a former president.—A vote of condolence with Mrs. Whistler was unanimously passed.—Mr. Mayo Collier showed a case of Abductor Paralysis of the Left Vocal Cord in a young woman, the cause of which was undetermined.—Mr. Lennox Browne opened a discussion on the Conditions of the Throat and Larynx Simulating and Predisposing to Tuberculosis. He began with the statement that although it did not so frequently fall to the lot of the laryngologist to decide doubts as to the tuberculous, non-tuberculous, or pre-tuberculous condition of a throat or larynx as was the case with physicians devoting themselves to disease of the chest the responsibility was no lighter nor was the issue less vital. It was, however, a fact that occasionally the prodromata of tuberculosis could be discerned with the laryngeal mirror before the ear could detect them with the stethoscope. In such circumstances it was possible to arrest the disease in the higher situation. Dismissing shortly instances of simple inflammations, of syphilis, and of lupus in the larynx which might be mistaken for tuberculosis attention was drawn to the influence of nasal obstruction and faucial irritation in bringing about conditions not only liable to be mistaken for tuberculosis but as distinctly forerunners of that disease. Many cases were reported showing that there were no definite laryngeal evidences which could be accepted as criteria of a tuberculous condition or tendency thereto and the same might be said with regard to physical signs in the chest and even of the bacteriological features, for one case was related of a patient in whom, with a history of hæmoptysis, want of resonance, moist râles, and old adhesions, together with the presence of bacilli, complete recovery of health took place after efficient treatment of faucial irritation. In this case an eminent physician, without committing himself to the statement that the patient was free from the danger of tuberculous trouble, was of opinion that "looking at the progress of the case the consolidation had been mainly of a broncho pneumonic nature set up by the violent cough from which the patient had suffered and which had been so remarkably checked" by faucial and laryngeal treatment. The indications for treatment of the class of case considered were: (1) to clear away all obstruction to free nasal respiration; (2) to remove all source of irritation in the palate and fauces; (3) to correct the products of catarrh by suitable intra-laryngeal treatment (Mr. Lennox Browne preferred sprays of guaiacol diluted 50 per cent. with almond oil carried deeply into the larynx and trachea under pressure); and (4) while recognising the value of the open-air treatment he thought a warning was due not to surrender entirely, as there was a tendency to do, attacking the disease by drugs, and especially where, as was the case in the throat, the site of infection was well within reach.—Dr. Thorowgood observed that prominence of the arytenoids and infiltration of the commissure were valuable indications of pulmonary tuberculosis, with which disease also an anæmic condition of the pharynx and laryngeal region was often associated.—Dr. J. Macintyre (Glasgow) expressed his belief in a pre-tuberculous condition in the larynx before a bacillary diagnosis could be made.—Mr. Mayo Collier spoke of the increasing rarity of tuberculous affections the higher the respiratory tract was ascended.—Mr. St. George Reid discussed the significance of micro-organisms in sputa, notably of the micrococcus tetragonus, as a possible forerunner of tubercle bacilli.—Dr. Dundas Grant spoke of cases which simulated tuberculosis.—The discussion was continued by Mr. Foster Palmer, Dr. P. Abercrombie, Mr. Wyatt Wingrave, and the President.—Mr. Lennox Browne replied.

Forfarshire Medical Association.—An additional meeting of this association was held in the University College, Dundee, on March 7th, Dr. C. Templeman, the Vice-President, being in the chair.—Mr. D. M. Greig showed a patient, a man, after Excision of the Left Upper Jaw for Sarcoma and pointed out the slight deformity following such an operation.—Mr. Greig also showed a boy with Coxa Vara, pointing out the altered movements of the hip-joint and the attitude in standing and lying which was exhibited by patients suffering from this affection.—Mr. Greig also showed several specimens: (1) The Upper Jaw with Tumour attached removed from the patient previously shown; (2) a Femur removed by Amputation for Acute Osteomyelitis; and (3) two specimens with Loose Bodies in the Tunica Vaginalis Testis removed after death from a case of Lympho-sarcoma.—Professor C. R. Marshall read a paper on the Nitrites and Allied Substances, giving his classification of them and illustrating by means of the blackboard and sphygmographic tracings the actions of the members of the various classes. He explained how it could be shown by experiment that these substances only acted on the blood-vessels and not on the heart. He also pointed out the various steps that had been taken in order to find a substance with a similar action to nitroglycerine or glycerol-nitrate but which had a more prolonged or lasting action. The toxic effects of these substances were then shown to be due to their power of forming methæmoglobin in the blood and the sodium nitrate was in doing this more rapid than nitro-glycerine. The therapeutic uses of these substances were next touched on—in angina pectoris, in cardiac failure, and in arterial sclerosis.—Professor A. M. Stalker, in some remarks on the paper, emphasised the beneficial effects of iodide of potassium in arterial sclerosis.—The Chairman also commented on the paper and Professor Marshall replied.—Dr. George Whyte gave an account of a case of Corrosive Sublimate Poisoning which had resulted in recovery partly due to vomiting being induced early and partly to its solubility in alcohol. The quantity taken was equal to 9 6 grains. The symptoms, severe vomiting and purging, were treated by 20 minims of tincture of opium every four hours to begin with. The patient resumed his occupation on the fifth day after taking the poison.—Professor Marshall and the Chairman made some remarks on the subject and the difficulty in knowing the exact amount taken.—Professor Stalker gave notes of a case of Subacute Endocarditis which he had had under his care. The case showed some difficulty in the diagnosis. There were a persistent temperature and some cough, and later a mitral systolic murmur was made out, but for a time the case resembled one of pulmonary tuberculosis. There was no rheumatic history and the case did not present the appearance of a cardiac case.—Professor L. R. Sutherland showed the Heart from this case which had vegetations in the mitral cusps. Several of the chordæ tendineæ had given way, causing the valve to flap during the heart's action and infect the endocardium in the auricle. He pointed out that the orifice, though in life it must have been narrowed, still admitted two fingers. He considered that the separation of chordæ tendineæ was not such a rare affection as was generally made out.—Dr. W. E. Foggie emphasised the importance of watching the temperature in such cases.

Folkestone Medical Society.—A meeting of this society was held on March 2nd, Dr. T. Eastes (Vice-President) being in the chair. The minutes of the last meeting were read and confirmed. Mr. H. A. Powell then played "Rule Britannia" and the members sang the chorus with much enthusiasm. A musical programme was then gone through and Dr. C. E. Perry, Dr. Eastes, Dr. E. Norton, Mr. A. J. Gore, and Mr. Yunge-Bateman sang, while Mr. W. F. Chambers played the mandolin and Dr. Chubb the flute. Dr. J. H. Ewart gave a recitation and Mr. Thornton Gilbert a demonstration on card tricks and thought-reading. After "Soldiers of the Queen" had been sung by Dr. Perry a collection was made on behalf of the Royal Army Medical Corps Fund and the sum of £2 15[illegible] was collected. The meeting was one of the most [illegible] the annals of the society.

Reviews and Notices of Books.

A Text-book of Physiology. By WINFIELD S. HALL, Ph.D., M.D. Leipsic, Professor of Physiology, North-Western University Medical School, Chicago. Illustrated with 343 Engravings and six Coloured Plates. London: Rebman, Limited. 1900. Pp. 671. Price 20s. net.

IT speaks well for the progress of education in America, as well as in this country, that the author of the volume before us, which is the most recent work on physiology, should expect that the student who takes it as his text-book has received what may be termed a liberal education, that he is familiar with the elements of physics, that he has acquired a fair knowledge of mathematics and of chemistry, and that he only requires to be reminded of recent work in histology. Without this amount of preliminary education he will hardly be able to comprehend the reasonings or the clinical applications of modern physiology. It could not be supposed that in the compass of less than 700 pages the varied functions of the body could be equally satisfactorily given. If some are dilated upon others are curtly treated, and it must rest with the individual teacher to determine what subjects he considers it to be most important for a student to know. For example, as a rule we think too much space is devoted to the special senses in text-books, and Dr. Hall has done wisely and well for the ordinary student or general practitioner in curtailing the chapters on these organs. On the other hand, he has dwelt at much greater length, and with advantage, upon the processes of digestion, upon the functions of circulation and respiration, and upon the nervo-muscular apparatus.

Dr. Hall's Physiology is valuable because it presents to the reader the physical side of the several functions to a large extent, and at the close of some of the sections problems are given with the mode in which they should be worked out. Thus, to give an example, the following amongst other problems are required to be solved in regard to the circulation: (*a*) How much (work) does the left ventricle perform in each systole if 120 cubic centimetres of blood are ejected against 14 centimetres of pressure? Answer: $W = 13.6 \times 120 \times 14 = 22{,}848$ gramme centimetres (*b*) How much work does the heart perform at each systole if the right ventricle expels the same quantity of blood against two-fifths as great pressure? Answer: $W = [13.6 \times 120 \times 14] + [13.6 \times 120 \times \frac{2 \times 14}{5}]$ or $\frac{7}{5}$ of work done by left ventricle alone $= 31{,}987$ gramme centimetres. *In speaking of the cause of the sounds* of the heart Dr. Hall can scarcely be said to commit himself positively to the opinion—now, we thought, agreed upon by all—that the second sound is caused by the closure or sudden tension of the semilunar valves, for he only says that the cause of the second sound "is quite generally interpreted in that way"; but in regard to the first sound he is positively heretical, for he does not admit that the auriculo-ventricular valves have anything to do with it. He gives four factors—viz., vigorous muscular contractions, friction of blood rushing through the semilunar valves, friction of heart incident to its change of shape within the pericardium, and, lastly, friction of heart against neighbouring structures in the thorax incident to its change of position in the thorax; but if the second sound is essentially caused by the sudden tension of the semilunar valves we can scarcely discard the bicuspid and tricuspid valves as of no importance in the production of the first sound. The whole of the section on the Circulation seems to be short, and, if only to introduce the name of Harvey to the student, we should have liked to see a line or two devoted to the "proofs of the circulation of the blood" as well as to the mention of other circumstances than the coagulation of the blood by which death from hæmorrhage is prevented.

A small and handy instrument is depicted, which Dr. Hall names the "hæmatocrit," by means of which the proportion of the corpuscles can be determined by centrifugal action. A coloured plate shows the varieties of blood-cells, though, perhaps, properly they should be called blood corpuscles. These are (1) normal red cells, (2) normoblasts, (3) microblasts, and (4) megaloblasts. Another coloured plate gives the varieties of leucocytes. These he names (1) polymorphonuclear neutrophiles; (2) myelocytes; (3) eosinophiles; (4) eosinophilic myelocytes; (5) large lymphocytes; and (6) small lymphocytes. In regard to the coagulation of the blood the author adopts the explanation advanced by Schmidt and Hammarsten that it is due to the nucleo-albumins prothrombin and thrombin. Both of these are derived from the katabolism of nuclei acting in presence of the alkaline earths on fibrinogen, and the fibrinogen is derived from cytoplasm that has successively generated cytoglobulin, preglobulin, and paraglobulin.

We like the mode in which Dr. Hall has attacked the several subjects. As a rule there is a short histological introduction which is well illustrated by figures usually borrowed from well-known and accredited sources, such as Klein, Schäfer, Piersol, and others of equal reliability, but it is evidently anticipated that the student has already completed a course of histology and hence such subjects as the internal ear and retina only occupy a page or two.

If we select such a subject as respiration, we find there is first a short introduction showing the object of respiration and giving its comparative physiology and its performance through the skin, by means of gills, and by lungs. No allusion is made, however, to the tracheal respiration of insects. Then the mechanical phenomena of respiration are considered, and it may be remarked in passing that the author regards the costal type of respiration observed among women of European races as a peculiarity developed by a mode of dressing which hampers the movements of the diaphragm while permitting the elevation of the ribs, a view to which we should be disposed to demur. There is a physical introduction giving the solution of various gases in liquids, which is followed by a section on the Mechanical and Physical Features of Respiration. Original drawings are here given of the stethograph and thoracometer, of the belt spirograph and the chest pantograph, with the graphic tracings obtained from their application to the chest, and there is an original and ingenious diagram showing the relations of tidal to complemental reserve and residual air in the acts of respiration. A section on the Chemistry of the Respiration follows, and a section is devoted to the Control of the Respiration, in the course of which experiments are briefly given from which the functions of the nerve trunks and centres implicated in respiration are deduced. The rest of the chapter is occupied with the Chemistry of Respiration.

It is remarkable that the author nowhere alludes to the average number of respirations per minute, or to the relation of the number of respirations to the number of cardiac beats, or to the modifications in number that are consequent on exercise, food, sleep, and other conditions. We have noticed some want of care in the correction for the press—Hammarsten, for example, being twice spelt erroneously—but as it is a first edition and the errors are sufficiently patent and are not of much importance we forbear to mention them, since they will no doubt be corrected in the next edition. In the meanwhile English students and teachers may purchase the work with the certainty that they will obtain a thoroughly sound and reliable exposition of the present state of physiological knowledge.

Clinical Studies in Vice and Insanity. By GEORGE R. WILSON, M.D. Edin., Medical Superintendent, Mavisbank Asylum. Edinburgh: William F. Clay. 1899. Royal 8vo. Pp. 234.

THE relations of insanity and vice to the social and hygienic conditions under which we live have attracted much attention in recent years. In Professor Clifford Allbutt's System of Medicine (vol. viii.) Dr. Charles Mercier has published a most important memoir on the subject of insanity, vice, and crime, the inclusion of which in a System of Medicine is an indication of the direction in which the current of psychological medicine is moving. Dr. Wilson's work is conceived on somewhat different lines, and though the main thesis is devoted to the morbid mental and moral conditions resulting from alcoholism the work has in its limited sphere a distinct value and usefulness. Part I. deals with drunkenness and alcoholism and contains evidences of careful thought and observation. The practical diagnostic sign of drunkenness is laid down as the inability of the patient to control his habit. "Drunkenness is a disease which primarily affects the purposive functions. It spreads so as to involve parts of all the functions of intelligence ...... and the lesion is of progressive nature." The effect of this dissolution of mental and moral capacity is that the patient sinks to the level of a being of a lower order of intelligence while the general character grows childish and puerile. Instances are given in support of this statement and the method of treatment of drunkards is then briefly dealt with.

The alcoholic diathesis is next touched upon. As the result of inquiry it is stated that what may be called "low-class" drunkards are probably moral imbeciles, but that the average drunkards, who are in a large majority, are neither more weak-minded nor more strong-minded than their neighbours. Interesting clinical accounts and histories follow of various classes of alcoholics—e g., high-class, average, and degenerate alcoholics. There is much interesting information in these histories, easily and pleasantly written in a somewhat discursive vein. A clinical study of insanity from the records of 15 cases follows and concludes the work. The chapters comprising this part of the work deal with cases of special interest, eight being of male and seven of female patients, each illustrating some interesting feature, social or medical. The work is on the whole suggestive, but there are a dogmatism and a directness of statement and opinion in it which make it an exposition of the author's individual views rather than a presentation of the various difficult and controversial facts and views regarding insanity and crime which are so strongly pressing on modern public opinion. It will be read with interest by alienists and by intelligent laymen who are interested in the medico-sociological aspects of insanity and crime, and should meet with success as a useful little introduction to the subject.

Physiology: A Manual for Students and Practitioners. By HOWARD D. COLLINS, M.D., Assistant Demonstrator of Anatomy, College of Physicians and Surgeons, Columbia University, New York; and W. H. ROCKWELL, jun., M.D., Assistant Demonstrator of Anatomy, College of Physicians and Surgeons, Columbia University, New York. Series edited by BERN B GALLAUDET, M D. Illustrated with 153 engravings. London: Henry Kimpton. 1900. Pp. 323. Price 7*s*. 6*d*. net.

THE majority of teachers of physiology appear to find it requisite to write a compendium of their lectures, which may serve the students who attend their classes for home study, which shall contain the more important facts which it is desirable to remember, and which shall form a ground-work of facts that in their oral discourses they can supplement and expand. In this country there are several such manuals, and the professors at the different universities in America are beginning to pursue the same plan. By the steady avoidance of doubtful facts and of theoretical views a very considerable quantity of information can be compressed into a small space, and in reading the present volume it seems to us that much discretion has been exercised in the way in which each subject is handled. The chapter on Respiration, though short, contains most of the facts which the student needs to know, though we should be inclined to demur to the statement that at the close of each expiration the vagus filaments are mechanically pinched. In the section on Circulation it is stated that the non-regurgitation of the blood from the auricles into the veins is due to four causes—the insufficiency of the auricular contraction to produce a reflux, the contraction of the muscular coat of the great veins near the heart, the opposition of the weight of the incoming blood, and the opposition offered by the valves in the veins. But regurgitation is often seen in patients under chloroform when the force of the auricular contraction must be weakened and when the influence of the valves can be in no way interfered with. In reality the second of the above-mentioned causes is the most important. The pulse tracings are not satisfactorily executed and the dicrotism of the normal tracing is not referred to at all. The danger of compression to too great an extent is, of course, that important points may be overlooked. We notice that the vascular glands are all dismissed in ten lines with the bald statement that they agree in having no ducts, that they do not seem to be associated in either secretion or excretion, and that they have no definite functions, though their extirpation is attended with serious results. An opportunity is here missed of impressing upon the student the probability of internal as well as of external secretion. The adrenals are not even mentioned. The measurements are correctly given and the book will hold a good position amongst other works of the same size.

JOURNALS.

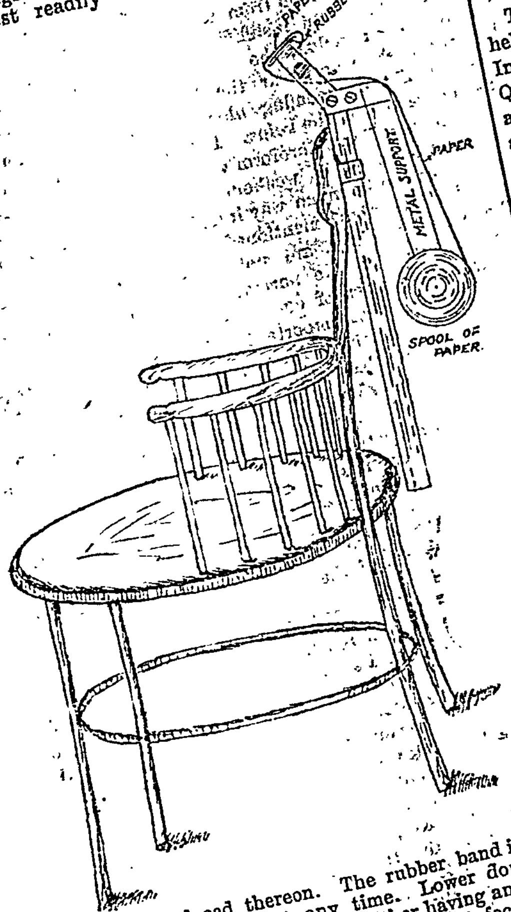
The *Veterinarian* for February commences with a couple of translations of lectures delivered by Professor Cadiot of Alfort, these being rendered into English by Mr. John A. W. Dollar, M.R C.V.S, the subjects chosen being Blennorrhœa in the Dog and Amputation of the Penis in the Horse. The symptoms and treatment of the former are fully discussed and in the article upon the latter the various methods of operating, sequelæ, &c., are thoroughly entered into. Locomotor Ataxia in the Horse is commented upon; there is an original article by Mr. S. N. Ranina, an Indian graduate of the Bombay Veterinary College, on the Inoculation of Horses for the Preparation of Anti-plague Serum, and a continuation of an article on Sheep Scab summarised from the American Government report on the subject. Under "The Month's Progress" are extracts of interest from foreign literature. A report of the proceedings of the Council of the Royal College of Veterinary Surgeons and reviews of new books conclude the number.

The *Veterinary Journal.*—The February number of this journal contains editorial comments upon the inequality of the preliminary educational test in England and Scotland required to be passed by a student before entering any of the veterinary colleges. Original papers are written upon the Unsexing of Animals and Oöphorectomy in the Mare (a further comment on which we publish elsewhere), Non-contagious Skin Affections, and Certain Laboratory Methods for the Diagnosis of Certain Micro organismal Diseases.

New Inventions.

A HEAD-REST.

THE objections to the head-rest on a barber's chair are manifest and manifold. The same rest is used for any number of people suffering possibly from all manner of skin and other diseases. The material (cloth, velvet, or leather) which is used to cover the wooden rest becomes the possible disseminator of various contagions. The head-rest described below is free from this danger. Instead of a hard wooden rest covered with cloth or some such material a piece of rubber band hung from two points (on the principle of leather springs or hangers for carriages) is used, so that the rest readily conforms to the shape of the head when placed thereon. The rubber band is detachable and can be washed at any time. Lower down than this rubber rest is a spool of paper, either having an oiled surface or having been saturated with some disinfecting medium. This paper is perforated in suitable lengths so that it can be torn off as required. The paper is taken from the spool (as is shown in the above illustration) and is passed over the rubber band and then secured. The person who is being shaved rests his head on the paper which covers the rubber band. When the operation of shaving is completed the paper which has been used is torn off and a fresh piece is substituted by simply pulling paper off the spool of the necessary length. The papers can bear distinctive numbers, so that they can form a check on the assistants in the shop as to how many people they have attended to. The inventor of the head-rest is Mr. F. B. Smith, architect, of Port Talbot.



A NEW CHIMNEY COWL.

WE have received from Mr. John Spring, of 413, Cleethorpe-road, Grimsby, a photograph and description of a new pattern of chimney cowl, terminating above in four lateral outlets directed to any four equidistant points of the compass. Each outlet is covered by a sloping (nearly vertical) door or flap hinged at a point above its upper margin, each pair of opposite doors being rigidly connected to one another by means of the bars from which they are suspended. When the air is still each door stands out from the corresponding opening in the cowl for a distance of three inches at the bottom, diminishing to one and a half inches at the top. When a gust of wind strikes a door it shuts it and opens the opposite or leeward door three inches wider. A strip of indiarubber along the bottom edge of each opening renders the closing of the door noiseless. There are no internal parts to get out of order, and the sweep's brush can be passed right in.

THE IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.

THE St. Patrick's festival dinner of this association was held at the Hotel Cecil on March 17th, the President, Inspector-General Lloyd, R.N., honorary surgeon to the Queen, being in the chair. This was one of the best attended and most successful dinners of this important and increasing association. A large number of guests were present, the guests of the evening being Mr. W. H. Lecky, M.P., and Sir Dennis Fitzpatrick, K.C.S.I. After the health of the Queen and Royal family had been proposed and enthusiastically received Dr. J. Holmes Joy gave the toast of "Our Defenders," which was responded to by Surgeon-General Jameson, C.B., Director-General of the Army Medical Service, Fleet-Surgeon Delmege, M.V.O., and Surgeon-Captain Bourke. "Our Guests" was proposed in an able speech by Mr. P. J. Freyer, who was frequently interrupted by outbursts of applause, and responded to by the Right Honourable W. H. Lecky, M.P., and Sir Dennis Fitzpatrick, K.C.S.I. The toast of "Ourselves," proposed by Dr. W. S. Playfair, was responded to by the President. Dr. T. Monillot gave the toast of "Our Lady Guests," for whom Mr. T. Lean Wilkinson responded. During the evening a selection of Irish songs was given by Mr. W. Nichol and Miss Elsie Nichol which was much appreciated. Mr. J. J. De Zouche Marshall also contributed much pleasure to the association by singing two appropriate and well-rendered Irish songs. Mr. J. W. Ivimey accompanied at the piano. Much credit is due to the dinner secretary, Dr. Swanton, for the success of the evening, also to Mr. Freyer and Mr. James Stewart, the general secretary. During the evening the following telegram was forwarded to Her Majesty:—

THE QUEEN'S MOST EXCELLENT MAJESTY, WINDSOR CASTLE.

MADAM,—On behalf of the Irish Medical Schools' and Graduates' Association here assembled I beg to offer your Majesty our heartfelt gratitude for your Majesty's gracious recognition of the services rendered in South Africa by your Majesty's Irish soldiers, our fellow-countrymen, and for the highly prized permission to wear the shamrock on Saint Patrick's Day.

I humbly convey to your Majesty our full appreciation of your Majesty's gracious thought of our country at this time and earnestly pray that your Majesty's approaching visit to the Irish metropolis may be all that our loyal Irish hearts can wish for our beloved Queen.

I am, your Majesty's most faithful subject,
INSPECTOR-GENERAL LLOYD, R.N.,
Honorary Surgeon to your Majesty, President of the
Association.

Hotel Cecil, St. Patrick's Day.

The following is a copy of the reply which through ar
accident was not delivered during the dinner:—

TO INSPECTOR-GENERAL LLOYD, HOTEL CECIL.

The Queen desires me to thank the members of the Irish Medi
Schools' and Graduates' Association for their loyal and kindly mess
which alludes to the national appreciation felt at Her Majesty's
mission for the future wearing of the shamrock by her Irish troop
this day.

The Queen is gratified by their good wishes expressed for her co
visit to Ireland, to which event Her Majesty looks forward with
pleasure.

(Signed) Bi

A telegram was also sent to Lord Roberts who had
guest of the society on a former occasion:—

Accept our Patrick's Day wishes. Kindly convey them t
countrymen under command. We drink health, safe return.
LLOYD, President Irish Medical Graduates, n
Hotel Cecil.

THE LANCET.

LONDON: SATURDAY, MARCH 24, 1900.

THE proceedings of the meetings of the Executive Committee which occur in the interval of the sessions of the General Medical Council are of interest as showing the continuity of the work of the Council in respect of certain questions in which the profession is interested. Several such questions came up for consideration at the meeting of the Executive Committee on Monday, Feb. 26th. The vacancy on the Executive Committee created by Mr. Brudenell Carter ceasing to be a member of the Council was filled by the appointment of Dr. Donald MacAlister, the representative of the University of Cambridge on the Council. There can be little doubt that this appointment will be approved by the Council at large. Dr. MacAlister takes a very active and valuable part in the proceedings of the Council, especially in his capacity of chairman of the Business Committee. It is obviously convenient and proper that the chairman of such a committee should be a member of the Executive Committee. Another personal matter of much interest is to be noted in the proceedings of the committee. Mr. Farrer, whose firm have acted as the solicitors to the Council since 1859, and who has personally filled the office since 1886, has in a letter to the President expressed his wish to resign at an early date on the score of age and the state of his health. At the request of the Council Mr. Farrer has consented to hold his office till the next meeting of the Council, when a successor will have to be appointed. The amount and nature of the legal business of the Council alter with the development of the Council's work and require knowledge and qualities of a kind which every good solicitor does not necessarily possess. The Council must be careful in its selection of a successor to Mr. Farrer. Much of the power for good of the Council depends on its lawyers and a good and strong solicitor may save it money and gain it credit. It is impossible to deny that in some recent legal proceedings the Council has not appeared to such advantage as it usually did in earlier days. This may not be altogether the fault of its lawyers. The Medical Acts are so loosely drawn that they admit of much bad litigation; but this is only another reason for having the best legal advisers who can be found.

The minutes of the Executive Committee are not very explicit in regard to the probability of legislation for amending the penal powers of the Council and of the medical bodies which grant degrees and diplomas, but the committee carried a motion authorising Mr. Farrer and Mr. Muir Mackenzie to prepare a Bill "in accordance with the clauses submitted to and approved by the Council on Dec. 2nd, 1899." We may remind our readers that the President at the meeting in December was requested to f the same to the Privy Council and to express the desire of the General Medical Council that the Government should prepare or support a Bill for passing them into law. It may be assumed, from the statement made by the President of the General Medical Council to the Executive Committee and from the Committee's instructions to the lawyers, that Sir William Turner has had satisfactory assurances of support from the Government. So it may be hoped that the clauses in question, together with one for securing that fines for offences under the Medical Acts shall be paid to the credit of the General Medical Council, instead of, as at present, to the credit of the Metropolitan Police, will before long become law. One of the great evils of a state of war such as the present is that it interrupts all ordinary legislation. It would be too sanguine to expect just now such an amendment of the Medical Acts as is implied in the clauses approved by the universities, by the medical corporations, and by the General Medical Council, but we may nevertheless hope for some modest measure of success.

A subject of some difficulty and of much importance is that of reciprocity in the recognition of medical qualifications between this country and Italy. The General Medical Council at its last meeting instructed the President to ascertain if the Italian Government had arrived at any fixed determination to alter the law by which hitherto British practitioners have been allowed to practise in Italy. The President called the attention of the committee to the fact reported to it, that the Italian Government has under its consideration a Bill to exclude from practice in its territory foreign practitioners belonging to countries which do not grant reciprocal rights. The committee requested the President of the General Medical Council to call the attention of the Privy Council to this fact, which will doubtless also be referred to the General Medical Council for its consideration in May.

Medical practitioners know too well that any carelessness on their part in answering letters of inquiry from the Registrar in regard to their addresses or other matters is apt to be followed by their removal from the Register under the 14th section of the Medical Act of 1858. Such removal, though easily set right, is felt to be a great inconvenience. At the recent meeting a gentleman who had been removed under this clause applied to have his re-registration antedated "on account of serious legal disability under which he would suffer loss owing to the absence of his name from the Register from 1897 to Feb. 5th, 1900." The resolution of the Council was to the effect that the name was now restored and had been re-registrable at any time since its removal. This shows, what we should expect, that the Council cannot antedate a re-registration, and it emphasises the importance of more attention on the part of practitioners with regard to answering the letters of the Registrar.

We see with satisfaction that in noting the introduction of the Midwives Bill into Parliament the Executive Committee have represented to the Privy Council that the Bill does not make provision as advised by the General Medical Council for requiring licensed midwives to apply for qualified medical assistance in every case attended by danger, or disease on the part of the mother or child, and have expressed to his lordship their opinion that such a provision is one of imperative necessity for the safety of lying-in women. We venture to hope that upon such a grave expression of opinion by the Executive Committee of the General Medical Council the insertion of such a provision in the Midwives Bill will follow. There are many inherent objections to the Bill with such an addition; without it we regard the measure as unmitigatedly dangerous.

WE have before us a copy of the report and certificate submitted by an alderman of the Northamptonshire County Council under the Housing of the Working Classes Act of 1890, recommending his council to sanction the adoption of Part III. of the Act by the Brixworth District Council in respect of a Northamptonshire village named Spratton; and we have also before us an account, taken from a local newspaper, of the county council's debate on the adoption of the report. These documents form interesting reading. The Act in question has been of substantial benefit in metropolitan areas and possibly in urban districts outside London, but rural districts have hitherto made but little, if any, use of Part III., a portion of the Act which particularly applies to them. Part III enables local authorities to build lodging-houses, an expression which includes separate houses or cottages for the working classes. In rural districts the local authority is the district council, which may, with the sanction of the county council, acquire land, compulsorily if need be, build, let, regulate, and if necessary sell again, houses for working men, raising the money for these purposes by a rate levied on its district, or on such portion of it as may appear just. There are various reasons why rural districts should not hitherto have availed themselves of these provisions. Most of our villages are peopled by agricultural labourers and afford habitations to a diminishing rather than an increasing population, while a large proportion of them are "close" villages. With regard to this term we cannot do better than cite two quotations made in the report before us from a document published by the Royal Commission on Labour of 1892-93. They are: "In villages which are owned, chiefly or entirely, by one landlord, or where cottages have been provided as part of the equipment of a landed estate for the housing of those who work on that estate, the cottages are almost invariably superior in character to those in open villages, or wherever they are held apart from land, and of owners who depend to some extent upon cottage rents for their living." "The action of the local sanitary authority, though vigorous in some districts, is in many places ineffective, and it is everywhere impeded and sometimes arrested by the knowledge that the owners of insanitary dwellings have not the means to remedy the defects, and that the consequences of closing such dwellings would be to make the present inhabitants homeless." Spratton, we may add, is not a "close" village.

At the meeting of the Northamptonshire County Council the idea of a local body supplying dwellings for the working classes in a rural district found one or two strenuous opponents, some of whose arguments have force, although we cannot think that they ought to prevail, but the landed interest as represented on the council found an enlightened spokesman in Lord SPENCER, who strongly supported the resolution put forward on behalf of the village under discussion. His lordship professed a warm interest in the experiment about to be made, referred to his observation of the needs of rural districts in Ireland, and pointed out that as far as Northamptonshire went his own interests as a ratepayer were largely affected by the subject of discussion. His liberal-minded advocacy of the needs of Spratton had no doubt considerable effect on the result of the debate, which ended in the resolution for the issuing of the necessary certificate to the district council being carried by a large majority. Spratton appears to be a good instance of what is known as an "open" village. Its 187 dwellings, of which 147 are cottages, are said to be owned by no less than 83 different persons, some of them quite unable to spend money on improving their property. The majority of the insanitary tenements were originally erected by squatters whose occupation of neglected land by the roadside had been acquiesced in until it became too late to dispute the ownership. Anyone acquainted with common lands in England where there is anything to support a population will recall instances of squatters' cottages and will have noted their inadequacy as dwellings. Frequently a neighbouring landlord bears the blame dealt out by hasty observers with regard to them. Of the cottages in Spratton five were reported as beyond being made fit for human habitation and four of these were overcrowded, while of 11, of which three were overcrowded, it was thought that they might be made inhabitable by repair. The remedy proposed for this state of affairs and now to be adopted includes the allowing of two months to the owners of the dwellings capable of repair in which to make them decent and sanitary, with the alternative of having them compulsorily closed; while in the case of the others a similar period is to be allowed to the tenant to find accommodation elsewhere, and they are then to be closed. Meanwhile the Brixworth District Council will raise the necessary funds in order to replace them with cottages of its own.

In the report already referred to, which was made by Mr. C. K. WOOLSTON, an alderman of the Northamptonshire County Council, with assistance, which he gratefully acknowledged to the council, from Mr. C. E. PAGET, the county medical officer of health, we note among the cogent reasons laid before the council to aid them in arriving at their decision the statement that no evidence was gathered by Mr. WOOLSTON to show that any plans for new cottages had been submitted to the local authority for approval, or that there was any intention on the part of any person to erect such cottages, or that any improvement of existing dwellings was in progress or in contemplation by their owners. We ought, perhaps, to add to what we have said about Spratton as an "open" village that its inhabitants are not purely agricultural or engaged in one pursuit; some of them are connected with working ironstone, a few with the railway, and one seems to be a bootmaker at Northampton. Good cottages are not "paying" property and the landlord who provides them as accessory to the occupation or working of his land is not necessarily able or willing to supply them for the use of men not employed in connexion with his own estates. In such instances, or in cases where the landlord (or landlords, should there be many) is neglectful or impecunious we conceive that it is the duty of the district council to obtain for the working men within its area suitable, sanitary, and inexpensive homes, and we recommend to district councillors in general the consideration of the action of their congeners in Brixworth. The guardians of this locality, we note, rendered aid to the Commission on Labour in 1892 by the "very complete tables" which they furnished for its information and an intelligent and liberal spirit would seem to prevail here with regard to questions affecting the public health and welfare.

THE subject chosen this year by Dr. F. J. WALDO for his Milroy Lectures, which have just been delivered before the Royal College of Physicians of London, is one full of interest and importance in preventive medicine. Epidemic diarrhœa, to choose one of its many synonyms, is a chief cause of the vast infantile mortality that has hitherto eluded the control of the public health reformer. It has not shared in the decrease that has taken place in this country in plague, cholera, tuberculosis, typhus fever, and small-pox, but has maintained its rate of mortality. A point brought out clearly by the lecturer was that its incidence was not necessarily influenced by the factors favourable to the spread of enteric fever—an observation of some moment when we consider the strong analogy that exists between the two diseases.

Epidemic diarrhœa has well-marked peculiarities which point to special methods of origin and distribution. Among them may be mentioned its main occurrence in the third quarter of the year, the terrible mortality it causes in children under five years of age, its urban incidence, and its prevalence in dry summers. One of the most interesting discoveries in its etiology was the demonstration by the late Dr. BALLARD that the summer rise of the disease did not commence until the mean temperature recorded by the four foot earth thermometer reached somewhere about 56° F. To this observation Dr. WALDO added one of almost equal significance in demonstrating the local distribution of the malady in counties. From the analysis of a vast array of statistics he arrived at the conclusion that diarrhœal diseases were first and foremost the result of strictly local conditions. To put the matter in another way, the great variation in the diarrhœal death-rate in different districts of one and the same county excludes climatic conditions as the essential factor in causation. Another suggestive feature in the history of the malady is the fact of its vastly greater incidence upon hand-fed as compared with breast fed infants. With regard to the ultimate origin of the disease Dr. BALLARD suggested the presence of a specific microbe or microbes with a probable habitat in the superficial layers of the soil. The theory now generally accepted is that epidemic diarrhœa is the result of the invasion of one or more micro-organisms, such as the proteus vulgaris, and various micrococci and bacilli, while several constant bacteria of the human intestine appear at times to acquire pathogenic properties. Our knowledge of the bacteriology of epidemic diarrhœa, however, is still in an imperfect condition and its prosecution is surrounded with great technical difficulties. Dr. WALDO has now come forward with a theory of causation that is in some respects novel, though he does not claim originality for it. He suggests that epidemic diarrhœa is probably due in no small measure to the pollution of street-dust by horse-dung. The chain of proof is admittedly imperfect, but it must be admitted that the theory explains many of the peculiarities that mark the natural history of the disease. Dr. WALDO'S words in his Milroy Lectures were: "In casting around for a possible source of what may be regarded as a manifold infection of epidemic character the idea occurred to me, as it has to others, that organically polluted dust might be the vehicle of distribution. A further consideration of the circumstances of the case led me to form the opinion that horse-dung may be the specific polluting material." The composition of the dust of towns—and it must be remembered that it is only in towns that epidemic diarrhœa is rife—plainly differs from the dust of country roads in one important particular—namely, in the infinitely greater proportion of horse-dung which it contains. With the wonderful power of penetration possessed by dust we are all familiar. It is universally diffused through every part of the town-dweller's environment and presumably where it goes it carries any organic germs with which it may have been charged. If the bacilli present in dry horse dung will cause diarrhœa Dr. WALDO'S supposition becomes feasible. The theory also explains why hand-fed children suffer especially. Milk, which forms the staple article of infantile diet, is freely exposed to invasion by town dust, both in the shop of the retailer and in the larder or cupboard of the consumer. As dust the contagious material would settle on surfaces or float in the air, and in either case would be washed away by rain, a fact that accounts for the diminution of diarrhœa in wet summers.

While on reflection it appears that other points in the etiology of the disease may be cleared up by assuming the cause to be the aerial distribution of dust charged with the infections of horse-dung, we do not need to be convinced of the correctness of the theory to approve of any pathology by which impetus will be given to the progress of street sanitation. The desirability of wide streets with smooth, impermeable roadways capable of frequent flushing, always apparent to medical men, will be more apparent to sanitary authorities after learning the tenour of the Milroy Lectures. The need of frequent and systematic town scavenging will be greatly emphasised, as well as of the absolute supervision of milk supplies from the udder of the cow to the mouth of the consumer. The necessity of approximately dust-proof larders will be evident, and even the substitution of mechanical for horse traction will be advanced. Whether the theory be ultimately established or otherwise it cannot fail to attract attention to the importance of street sanitation and the domestic storage of food. We hope to publish in full in early issues of THE LANCET Dr. WALDO'S Milroy Lectures.

Annotations.

"Ne quid nimis."

WINDOW CLEANING AND FLASH-LIGHTS.

ON March 20th the London County Council passed some by-laws which the Home Secretary has intimated his intention to approve. They deal with the custom of servants or other employés standing on window-sills for the purpose of cleaning windows or for any other purpose, at any height over six feet from the ground without a sufficient support. The penalty for breach of this by-law is fixed at £5 for the employer and £1 for the employé offending. The second by-law deals with those abominations which have recently come into use for advertising purposes—namely, flash- and search-lights. We have on previous occasions[1] expressed our opinion of these things and are sincerely glad to see that the Council has at last put its foot down. The following are the by-laws on lights:—

> No person shall exhibit any flash-light so as to be visible from any street and to cause danger to the traffic therein. Nor shall any owner or occupier of premises permit or suffer any flash-light to be so exhibited on such premises:
>
> "Flash-light" means and includes any light used for the purpose of illuminating, lighting, or exhibiting any word, letter, model, sign, device, or representation in the nature of an advertisement, announcement, or direction which alters suddenly either in intensity, colour, or direction.
>
> No person shall exhibit any search-light so as to be visible from any street and to cause danger to the traffic therein, nor shall any owner or occupier of premises permit or suffer any search-light to be so exhibited on such premises.
>
> The expression "search-light" means and includes any light exceeding 500-candle power, whether in one lamp or lantern or in a series of lamps or lanterns used together and projected as one concentrated light, and which alters either in intensity, colour, or direction.
>
> Any person who shall offend against any of the foregoing by-laws shall be liable for every such offence to a fine not exceeding £5.

We really seem to be getting within measurable distance of the time when London will be a comfortable city to live in. The by-law to stop street shouting which was passed upon Feb. 6th has now, we presume, become law. The German band, however, still flourishes, and the hawkers of newspapers still make night hideous with their unveracious screeching. But we are a slow-moving nation and cannot expect too much at once. Meanwhile, let us be thankful for what the London County Council has already done.

QUALIFICATIONS OF PUBLIC ANALYSTS.

UNDER the amended Sale of Food and Drugs Act a wider interpretation to the word "food" is given. The term now embraces any article which ordinarily enters into or is used in the composition or preparation of human foods, including flavouring matters and condiments. This will considerably increase the work of the public analyst and it is all the more necessary, therefore, that all future candidates for this position should possess suitable qualifications. The Local Government Board have for some time had this matter under consideration and have now issued a statement of their requirements in this respect. Intending candidates for public analyst appointments will now, if they have not previously held such an office, have to furnish proof of competent skill in, and knowledge of, analytical chemistry, therapeutics, and microscopy. To meet these requirements the Institute of Chemistry has added a special examination in therapeutics, pharmacology, and microscopy to be taken in conjunction with the analysis of food and drugs section of their final A.I.C. examination. The possession of this certificate together with the diploma of Fellowship or Associateship of the Institute has now been definitely accepted by the Local Government Board as sufficient evidence that the holder possesses the knowledge necessary for the office of Public Analyst. The value of microscopy in every class of analysis has been so long recognised that it should certainly form an important part of the training of analytical chemists. A general knowledge of therapeutics and pharmacology is desirable, not to say essential, for a public analyst, but it should be borne in mind, nevertheless, that he is not in any sense a medical man. Any questions of a therapeutic character based on the results of chemical analysis should be referred to the medical officer of health of the district concerned. In this connexion it is to be hoped that the number of samples of drugs taken under the Act will in the future be largely increased, as the purity of medicaments is of the utmost public importance.

THE AFTER-EFFECTS OF UNSEXING ANIMALS.

IN the *Veterinary Journal* for February there are two interesting articles upon this subject. One, written anonymously, treats of the subject in a general way, and the other, a paper read by Professor Hobday before the Lancashire Veterinary Medical Association, deals particularly with oöphorectomy in the mare. On the smaller animals—such as the pig, the sheep, the dog, and the cat—the operation has been practised for many years, but the unsexing of the females among the larger animals has been allowed to fall into disuse in England until somewhat recently. It is practised upon mares which are continually in œstrum, those which have nymphomaniac tendencies, and upon those which are pronounced kickers. In America it is done upon racing mares in order to ensure that they can be kept in good condition and can be brought to the starting-post without fear of œstral troubles when amongst other horses. For hunting mares of uncertain temper and known to be excitable and dangerous in the field it possesses the same value. According to the observations of Professor Hobday, who practically demonstrated the operation on a vicious mare before the members of the Lancashire Association, the vaginal method of operating is by far the best from all points of view, and the ultimate improvement in temper is much more likely to ensue in a young animal than in an old mare in which the habit of kicking has become firmly established. On the stallion the effect of the removal of the testicles in rendering the animal more docile and tractable for the service of man is too well known to need comment. Calves are usually unsexed when they are a few months old; the operation upon the female is then performed through the flank, but this operation is not regularly practised except in certain districts. The object is to make them fatten more quickly. In heifers and milkers the vaginal method is the best; with the latter the objects are to prolong and increase lactation, to cause the animals to fatten quickly, and at the same time to render the meat more palatable for human food. The average of successful results is very good. The pig is almost always operated upon when young; in some counties, particularly in Norfolk, Suffolk, and Essex, many dealers will not buy female animals that have not been spayed. The operation is often done by a travelling gelder, and so expert do these men become that it is no uncommon thing for the whole process, from the time when the incision in the flank is made until the wound is completely sutured, to occupy only 30 seconds, both ovaries and horns of the uterus being removed during that time. No antiseptic precautions are taken and the percentage of deaths is practically *nil.* It is a commonly accepted idea that unsexed pigs fatten better, that their flesh is more palatable, and that the bacon takes the salt better than when the animal is entire. In the sheep the male lambs are castrated, oöphorectomy in the female having completely fallen into disuse not only in England but on the Continent. The males of the canine and feline varieties are operated upon in order to curtail their wandering propensities and also in the case of the cat to do away with the very objectionable odour of the urine of the uncastrated "Tom." In the females oophorectomy, or frequently ovaro-hysterectomy, is performed in order to keep her from attracting friends of the opposite sex and prevent the consequent multiplication of species Avoidance of the latter point, can always be ensured, but if the bitch or cat has once had young ones or even been in œstrum this troublesome period is apt to occur again once or twice, although as a rule it is not so prolonged as when the ovaries are present. In the female cat, particularly the long haired breeds, there is another advantageous sequel in that they do not change their coats twice a year in the same manner as before; they remain in good coat at a time of year when other cats are losing their hair and generally looking out of condition. It has been said that the unsexed dog and cat become fat, lazy, and useless for all work, but both writers in this number of the *Veterinary Journal* assert that this is not the rule if the animals are properly dieted and exercised afterwards. The after-effect of the operation upon the shape of the head and neck is curious. The castrated male always takes the form of the female, the spayed female not being noticeably altered in appearance except in the case of the cat; in this animal an unsexed female, if operated upon when young, will often develop the head, size, and form of an uncastrated "Tom" In pheasants, too, it is said that a hen bird will acquire cock's plumage if the ovarium is pricked or twisted. What can be the cause of the influence exercised by the generative organs on these points, and why should not emasculation have the same effect on the shedding of the male cat as on that of the female?

---

[1] THE LANCET, Oct. 22nd, p. 1077, and Nov. 26th, 1893, p. 1418

A TESTIMONIAL TO THE RESIDENT MEDICAL OFFICER OF ST. GEORGE'S HOSPITAL,

For 25 years as resident medical officer at St. George's Hospital Mr. F. J. Marshall has exercised an influence at that institution not necessarily associated with his official post. In addition to the general supervision which he exercises over the working of the hospital he has been throughout the guide, philosopher, and friend of every house physician and house surgeon who has held office during this period. It is not surprising, therefore, that the past and present residents of St George's Hospital decided to commemorate Mr. Marshall's completion of 25 years service at the hospital. In furtherance of this object a dinner was held at the Café Royal on March 14th when Mr. Marshall was the guest of between 60 and 70 of his friends, every one of whom owed him some debt of kindness, hospitality, or advice incurred during the last 25 years. Dr. A. P. Sherwood of Eastbourne was in the chair by right of seniority, and the company included many of the surgeons and physicians to St. George's Hospital who had been in residence at various periods during Mr. Marshall's occupancy of office. Mr. W. H Bennett and Mr. Adams Frost were two of the four residents holding office when Mr. Marshall first went to St. George's, and those of later date included Dr. Lee Dickinson, Dr. Cyril Ogle, and Dr. A. C. Latham and Mr. George Turner, Mr. Marmaduke Sheild, Mr. H W. Allingham, Mr. W. C. Bull, Mr. H. B Grimsdale, and Mr. F. Jaffrey, to mention those only who are on the staff at St. George's Hospital. The chairman in a capital after-dinner speech described the apprehension with which the advent of a resident medical officer was viewed by the residents 25 years ago and the steps taken to insure his discomfort, steps hurriedly retraced when at the end of a few days it was realised that "one of the best fellows in the world" had taken up his abode at St. George's Hospital. Telegrams were read from past residents now at Wynberg Base Hospital, South Africa, from New Zealand, and from other quarters of the globe. At the conclusion of his speech the chairman presented the guest of the evening with a cheque for 100 guineas, which with a set of silver candlesticks and silver and onyx "pool," represented the testimonial. Mr. Marshall made a cheery and characteristic reply and, the ordeal of photography having been safely passed through, the company separated.

THE CEREBRAL SYMPTOMS OF TYPHOID FEVER.

Nervous and cerebral symptoms assume an important place in the symptomatology of typhoid fever and their frequency has led to the name Nervenfieber, which is one of the German synonyms for this disease. Headache is extremely common, while delirium and even acute mental confusion may be not infrequently present. The stage of convalescence may also be marked by attacks of nervous depression and exhaustion, and Professor J. M. Da Costa recently exhibited a case which had been free from notable nervous disturbance during the illness, but in which during the period of convalescence and about a week after the fever had subsided mild nocturnal delirium had set in, with mental confusion and hallucinations which, however, disappeared during the day. This condition eventually disappeared under suitable tonic treatment (syrup of hypophosphites with strychnine) and the ingestion of small quantities of alcohol (whisky) with food at short intervals. Dr. Thomas Claytor, Professor of Clinical Medicine at the Columbian University (D.C), reports three interesting cases of general convulsions occurring as a cerebral complication of typhoid fever.[1] The infrequency of general convulsions may be gauged by the fact that Murchison in his classical work "On the Continued Fevers of Great Britain" states that of 2960 cases of enteric fever admitted to the London Hospital in eight years convulsions occurred in only six cases. Dr. Claytor's cases are as follows. Case 1—The patient was a private soldier, aged 26 years, who was attacked with fever, headache, diarrhœa, and epistaxis in the Cuban campaign. He was admitted to hospital on the twentieth day of his illness, the temperature rising on occasions to nearly 106° F. He was slightly delirious at times. Numerous large abscesses on the body and the limbs followed subsidence of fever, and these were freely incised and evacuated. He was on the road to recovery and on the thirty fourth day of his illness "while apparently asleep he uttered a sharp cry, threw up his hands, and went into a slight general convulsion. The eyes were fixed and glassy; there was slight frothing at the mouth for a few seconds." He remained unconscious for ten minutes, and on recovering he said that he felt as though he had been dreaming. On the fiftieth day of the illness (convalescence having been established) he had a second and more serious seizure. "While sitting up in bed eating his supper he suddenly uttered a sharp cry, threw up his hands, fell over on his right side, and went into general convulsions" The convulsive movements were followed by a period of rigidity with the head and shoulders bent forward. In from 12 to 15 minutes the forearms were flexed and raised to the head, and slight twitchings with grinding of the teeth and drawing of the face to the left followed. The patient lay on his right side all night with the head and shoulders bent, the legs and thighs flexed, and the arms rigidly set in the attitude mentioned, and any attempt to change the position caused a return of the spasms. The jaws were firmly set and feeding was only possible by a tube passed into the œsophagus through the nose. He gradually recovered and was well in a few days Case 2.—A young soldier, aged 24 years, had enteric fever, and on the twenty-seventh day he became unconscious and had slight general convulsions. The breathing was very slow (four respirations per minute) and there was blood in the stools. Baths were frequently given and he ultimately recovered. Case 3.—The patient, aged 27 years, had intercurrent relapses of typhoid fever, lasting in all three months. There were delirium and profuse sweating on August 30th, 1899, followed by generalised convulsions on the next day with loss of conciousness. Eventually the patient recovered.

HONOURS TO THE MEDICAL PROFESSION.

UNIVERSAL satisfaction will be felt throughout the profession by the announcement made in the *Gazette* of March 20th that the Queen has been pleased to appoint Lord Lister to be Serjeant-Surgeon in Ordinary to Her Majesty, in the room of Sir James Paget, Bart., deceased. Mr. Frederick Treves has at the same time been appointed one of the Surgeons Extraordinary to Her Majesty. *Lord Lister's three immediate* predecessors in this distinction were, in the inverse order of their periods of office, Sir James Paget, Sir William Fergusson, and Sir William Lawrence, men everywhere recognised as among the foremost representatives of British surgery. Sir William Fergusson, whose eldest daughter has just passed away (March 16th, 1900), was serjeant-surgeon from 1867 till his death in 1877. The Queen has usually had two serjeant-surgeons, but on the death of Sir Prescott Gardener Hewett in 1891 no successor to him was appointed, and Sir James Paget, who was raised to this dignity in 1877, remained up to the end of his life the only serjeant-surgeon.

HEAT APOPLEXY IN THE ARGENTINE REPUBLIC.

LETTERS received from Buenos Ayres state that the average shade temperature in the city was about 90°F. for nearly the whole of the month of January, a maximum of 104° having been registered on several afternoons. This was 10° above the average of the last 16 years and there was no rain and very little dew. This wave of heat culminated on Feb. 4th in a shade temperature of from 98° to 104° F., a low barometer, and over 50 per cent. humidity. An extraordinary mortality began to occur on Feb. 3rd and 4th, when of a total of 226 cases of "heat stroke" attended by the Assistance Publique over 80 died, most of them dropping dead in the streets as if struck by lightning. At 2 P.M. on Feb 4th there were 50 dead bodies in heaps in the "patios" (yards) of the central office. On Feb. 5th and 6th the great heat continued and over 200 cases of sunstroke were registered. On Feb. 7th 296 cases were attended, but there were only 10 deaths. Up to 5 P.M. traffic was practically suspended in the streets which had a deserted, plague-stricken look. All Government offices, banks, and large establishments reduced their hours of work and no outdoor work was allowed between 12 noon and 4 P.M. The Government, moreover, appointed a committee of medical men to inquire into the remarkable mortality. Several meetings were held and the unanimou opinion of all the members of the committee was that the character of the attacks which proved fatal in so many cases during the five days Feb. 3rd to Feb. 8th proved that it was merely *coup de chaleur*, and that the high mortality had nothing whatever to do with the sporadic presence of the bubonic plague in the republic. Buenos Ayres enjoys a temperate climate and for 40 years, the period over which scientific meteorological observations extended, such great heat as that of the beginning of last February has been unknown. Hence the many deaths of the first day. The public and the sanitary authorities were unprepared. Very few of the better class succumbed, although many were attacked, and the high mortality among the poor might be put down to ignorance and dread of the plague. Feeling suddenly ill they were afraid to call medical aid, which, if they had plague, would mean instant removal to hospital and isolation of their homes. The municipal authorities, in conjunction with the Board of Health, are taking steps to increase the water-supply, to establish free baths for the poor, and to limit the hours of work during the summer season. The fortnightly report of the Municipal Statistical Bureau for the period from Feb. 1st to Feb. 15th of course included the time covered by this great "heat wave," and consequently presented some remarkable figures. In Buenos Ayres, a city of 795,000 inhabitants, there was a total of 1110 deaths during the period in question; of these 121 were attributed to "insolacion" (sunstroke) and occurred on dates as follows:—On Feb. 1st, none; on Feb. 2nd, five; on Feb. 3rd, 29; on Feb. 4th, 52; on Feb. 5th, 10; on Feb. 6th, six; on Feb. 7th, 10; on Feb. 8th, six; on Feb. 9th, three. The mortality from this cause then came to an end. The largest number of deaths entered under any one heading in the list was 196 attributed to cerebral congestion and hæmorrhage; under the other headings 86 deaths were attributed to "meningitis cerebral," 14 to tetanus, 48 to organic heart disease, 28 to endocarditis and myocarditis, and 184 to diarrhœa and enteritis. The daily deaths from all causes were 104 on Feb 1st, 124 on Feb. 2nd, 181 on Feb. 3rd, 197 on Feb. 4th, 79 on Feb. 5th, and 51 on Feb. 6th.

ANTI-VACCINATION TACTICS.

THE National Anti-Vaccination League is a body which possesses a vast amount of experience, is extremely energetic, and is not over particular as to its methods. In view of the forthcoming census the Bristol Branch of the Anti-Vaccination League has put forward a circular headed "Vaccination Census, 1900." This heading is obviously meant to insinuate that the Government is about to make an inquisition into the condition of the populace solely as to whether they are vaccinated or no. This point, however, may pass for the present and we may go on to consider the rest of the circular. It proceeds: "With a view to ascertain the feeling of the public in the District Ward as to vaccination and its compulsion you are respectfully requested to fill in 'Yes' or 'No' to the following questions. 1. Do you believe in vaccination? 2 Are you in favour of its being compulsory? 3. Do you consider your Member of Parliament should support a Bill to abolish the present practice of compulsory revaccination as a test for soldiers, sailors, police, school-teachers, post-office employés, and every other branch of the public services? 4. Have you met with any cases of injury arising from the use of the new glycerinated calf lymph? If so, please state particulars. Name. ...... Address. ... . Remarks. . ...." This document is to be filled up and to be handed to the collector. A correspondent who sends us one of these circulars, which he has filled up, sends us also three leaflets, which he says are issued as supplementing the polling paper. One of these leaflets is comparatively innocuous, being merely instructions as to obtaining exemption under the recent Act The leaflet, however, omits to state that the applicant must satisfy the magistrate that he has a conscientious objection Merely saying that he has is not enough Leaflet number two contains information about the legal hours for serving notices and leaflet number three is a reprint of some remarks by the Rev Hugh Price Hughes Mr Hughes's state of mind is exemplified by the fact that he feels, "as a Christian, the strongest *a priori* objection to a system which is essentially a compromise with evil A physician of the body has no more right to enter into a compromise with disease than I have as a physician of the soul to enter into a compromise with sin" We do not perceive the force of this argument, but it is in no way fair to take a poll of the opinions of persons more or less ignorant and to try to bias their minds by distributing statements of this sort Mr Hughes is welcome to his own opinion but he should not try to bias any other man's conscience or rather he should not allow his opinions to be so used

LACTESCENT ASCITES OF LYMPHATIC ORIGIN

AT the meeting of the Société Médicale des Hôpitaux on Feb 23rd MM Fernand Widal and Prosper Merklen communicated an important paper on this subject Many writers have considered milky ascites as of chylous nature on account of the presence of fat capable of being estimated chemically and seen as globules under the microscope They have pointed out the frequency of cancerous or tuberculous lesions of the abdominal lymphatics and thoracic duct But others have thought that the fat might be due to degeneration of extravasated substances In recent years several cases have been published in France of "non chylous milky ascites M Lion first showed that milky ascitic fluid might not contain any chylous elements[1] In a case of cancer of the ovary he found that the liquid contained an albuminous substance analogous to casein and no fat M Achard later published a case in which the effusion contained only a small quantity of fat and innumerable minute refractile granules not coloured by osmic acid and similar to those described in the blood in albuminuria by MM Widal and Sicard Finally, M Apert[2] published an example in a case of heart disease Under the microscope fatty globules were completely absent and very fine particles were observed only under a very high power Analysis showed 2 59 grammes of fat to the litre The distinction between chylous and non chylous milky ascites presents great difficulties A small quantity of fat is in favour of a non chylous form But in chylous ascites the quantity varies very much in different cases and even at different times in the same case The kind of leucocytes in the effusion according to MM. Widal and Merklen may show the lymphatic origin in certain cases of chylous ascites The following case is an example An alcoholic man, aged 50 years, had sub icteric conjunctivæ, œdema of the lower limbs, and ascites On tapping the abdomen nine litres of lactescent fluid were removed Only temporary relief—for 24 hours—was given, the fluid rapidly collected again and the patient died on the sixth day Abdominal puncture performed immediately after death gave exit to three and a half litres of lactescent fluid similar to that previously removed The fluid obtained during life was neutral of specific gravity 1010, and contained 1 45 grammes of fat per litre It did not coagulate spontaneously on standing, it became opalescent and a thick whitish sediment settled Microscopic examination showed no fatty particles, but abundance of leucocytes—90 000 to 100 000 per cubic millimetre Careful examination with eosin and hæmatein, thionine, and Ehrlich's triacid, showed neither polynuclear eosinophile nor basophile leucocytes Only uninucleated cells, of which some were of the type of lymphocytes, the others large and medium sized mononuclear leucocytes, were found The necropsy showed enlargement and cirrhosis of the liver and softening tubercles at the apices of the lungs There were no signs of peritonitis and no lesion of the abdominal lymphatics was observed The presence of only mononuclear leucocytes in the effusion was the important point These leucocytes could come only from the lymphatics Thus, in spite of the absence of apparent lesions of the lymphatic vessels the lymphatic nature of the effusion was shown M Merklen has recorded another case of chylous ascites in atrophic cirrhosis of the liver in which no other abdominal lesion could be found[3] In a number of cases of lactescent ascites which have been recorded leucocytes in considerable numbers have been observed But a study of the kind of leucocytes present has not previously been made, and consequently its bearing on the pathogenesis of certain cases of milky ascites has not been recognised

"THE SEXUAL QUACK"

OUR Birmingham correspondent writes —"In THE LANCET of March 11th attention is drawn under the above heading, at p 818 to the degrading practices of the sexual quack as instanced in a pamphlet published in India It is to be regretted that similar pursuits in this country mark the demoralising tendency of such literature and tend to corrupt the sense of public decency and propriety One arch offender in this respect will now have opportunity for reflection in the 12 months imprisonment imposed upon him at the Birmingham Assizes on March 15th Before Mr Justice Darling a man, described as 'Professor Wells,' a public lecturer, was charged with having used obscene and filthy language, and with having published an obscene book at certain lectures delivered by him at the Exchange Rooms The evidence was incontestable and the punishment was fitly awarded to this pest of society A considerable amount of warmth and acrimonious criticism by the local press was evoked by the judge's address to the reporters before the case commenced He warned them as to the discretion to be used in regard to the publication of the details, and told them that although for many purposes they were protected in doing so there was absolutely no protection to a newspaper for publishing offensive or indecent or obscene details, and any newspaper that did it might just as easily be prosecuted for it as anybody else This severe warning has been regarded as uncalled for and unnecessary in a well conducted and honourable press"

STATUS THYMICUS

DR M LAUB looks upon certain cases of loss of consciousness with coma supervening in young people as due to a condition associated with persistence of the thymus gland which is designated status thymicus In a recent issue of the *Wiener Klinische Wochenschrift* (No 43, 1899) he records the following interesting cases The first case was that of a youth, aged 17 years who was taken to hospital at midnight in an unconscious state, the breathing being stertorous, the face cyanotic, and the lips covered with froth The pulse was scarcely perceptible, the pupils were contracted and irresponsive to light and the knee jerks were abolished Unilateral convulsions, commencing in the right hand, occurred at intervals of from 15 to 20 min
The urine was free from sugar but contained a
The patient continued in a comatose state
the following day The necropsy reveal

thymus weighing 19 grammes, multiple hæmorrhages in the lungs, and small miliary hæmorrhages in the neighbourhood of the fourth ventricle of the brain. The spleen was hyperplastic and the heart and aorta were hypoplastic. The second case was that of a youth, aged 18 years, who was taken to hospital in an unconscious state with a full, strong pulse and a cyanosed face. The urine was albuminous with traces of acetone. Death followed in a few hours and the necropsy revealed an enlarged thymus and spleen. The lymphatic glands were hypertrophied and there was some œdema of the brain and the left lung. The third case was that of a young man, aged 23 years, who was admitted to hospital in a similar state. There was a history of alcoholic excess on the previous night. He survived a few hours and died without recovering from coma. The necropsy showed an enlarged thymus and spleen, while the lymphatic follicles at the base of the tongue were enlarged. The urine was albuminous. A condition of œdema with hyperæmia was found in the brain and meninges and the lower lobes of the lungs showed diffuse lobular pneumonic patches. Case 4 was that of a boy, aged 17 years, who had become unconscious and while in that state had passed his urine and fæces under him. The urine was albuminous and blood-tinged. He died in a few hours without recovering consciousness and the necropsy revealed an enlarged thymus gland, together with swelling of the lymphatic glands and œdema of the brain. There was some trace of inflammation of the small intestine. Dr. Laub thinks that the diagnosis of status thymicus can be made when a young person apparently in good health suddenly falls unconscious with or without any external cause, becomes comatose, and dies in a few hours. The spleen is generally found to be enlarged and careful examination may disclose a similar enlargement of the lymphatic follicles in the naso-pharynx and at the base of the tongue. A slight albuminuria may be present and the necropsy reveals an enlarged and persistent thymus. The exact causation of this condition is still obscure, there being some resemblance to uræmia.

THE DURHAM MEDICAL UNION.

DR. ALFRED COX has issued a pamphlet, reproduced from the *Medical Magazine*, dealing with medical organisation in the north of England and giving a history of the work done by the County of Durham Medical Union. We are glad to note that this pamphlet has been sent to every practitioner in the county of Durham. The author relates that during the last four years nine medical unions have been formed between Newcastle-on-Tyne and Middlesbrough for the purpose of dealing with ethical and economical matters. He adds that the County of Durham Medical Union furnishes an example, probably unique, of a combination of medical men "banded together to work out their own salvation on avowedly trade-union lines." Like the workmen's unions the object of this medical union is to obtain the best possible terms from their employers—by conciliatory means if possible, by a strike if necessary. But there have been painful backslidings. Some of the practitioners who were most anxious for immediate action and who by their impatience precipitated the crisis before the union was sufficiently strong were the first to give way and to break their pledges. The majority of the patients are miners and trades unionists. They generally paid 6*d*. a fortnight and this sum covered the cost of medical attendance for the entire household in each case, estimated by Dr. Cox at an average of four persons, an average which we imagine must be somewhat below the mark. After conciliatory measures had failed a circular was sent out in which the colliery surgeons declared that they would cease giving their attendance unless the subscription was raised to 9*d*. Many of the surgeons imagined that because the miners were themselves unionists they would approve the formation of a union by the medical practitioners. On the whole they did approve, but as they have fought for all the advantages which they have gained they thought it was only fair that they should in their turn and as employers test what amount of fight there was among the surgeons whom they employed. Where a bold front was shown, the miners to a large extent yielded and the amount of 9*d*. is now paid; but when met with timidity and hesitation they refused the increase, and then some of those among the medical practitioners who had been loudest in favour of a strike were the first to give in. So the advantage gained has been only partial, but 200 out of a possible 430 medical practitioners are now in union and good progress is being made every day. The workmen themselves are realising more and more that proper attendance cannot be given to a whole family for 1*s*. a month. The practitioner will either make his attendances and drugs fit with this monthly shilling or, if he does his work conscientiously, then he will be sweated by his patients. Formerly this cheap work was farmed out to unqualified assistants. This is no longer possible and a qualified assistant costs too much. Indeed, Dr. Cox remarks that now no medical man can plead poverty as an excuse, for it is most difficult to get qualified assistants even at the greatly increased salaries which are now paid. Altogether, though there are dark sides to the picture painted, it is in the main a hopeful sketch of the progress partially accomplished and promising greater advance in the early future.

THE STUDY OF TROPICAL DISEASES BY MEDICAL WOMEN.

A LARGE majority of medical women practise their profession abroad, and for the most part in India and tropical countries. It is, therefore, obviously a matter of the first importance that they should have facilities for gaining a knowledge of tropical diseases before leaving this country; for there are numerous diseases practically unknown in England which are endemic in hot climates, and these receive, as a rule, but scanty notice in the ordinary text-book or lectures on medicine. Up to the present the only opportunity for instruction in tropical diseases which has been available for medical women has been the course of lectures delivered by Dr. Patrick Manson at the London School of Medicine for Women. We understand that the committee of the Liverpool School of Tropical Diseases have now decided to admit to their classes qualified medical women on equal terms with men students. We are glad to hear of this decision, and feel sure that many medical women who intend to practise abroad will avail themselves of the great facilities offered by the Liverpool school for gaining a knowledge of the diseases which they are liable to meet with in their intended sphere of work.

THE OPEN-AIR TREATMENT OF TUBERCULOSIS.

THE Royal Medical and Chirurgical Society has issued as a separate publication[1] the full report of the discussion upon the Open-air Treatment of Tuberculosis which took place on Nov. 14th and 28th and Dec. 12th, 1899. There is thus afforded an opportunity for those medical men who are not Fellows of the Royal Medical and Chirurgical Society to make themselves acquainted with the opinions of many of those of their professional brethren who have devoted much time and study to the consideration of the newest—or perhaps we should rather say newly revived—method of treating tuberculosis. Nearly all medical writers from the time of Hippocrates downwards have insisted upon the value of pure air and good living as aids to health in the case of phthisical patients, but perhaps Bodington of Sutton Coldfield was the first of our countrymen in modern days to preach a doctrine then neglected but now almost universally received. We dealt fully with the discussion in the leading columns of THE LANCET of Dec. 23rd, 1899 (p. 1746), so we shall merely repeat here that the whole trend of the discussion was to extend the trial of the method, provided such treatment be carried out upon truly scientific and not commercial lines.

---

[1] Discussion on the Open air Treatment of Tuberculosis, Nov. 14th and 28th and Dec. 12th, 1899 (from vol. lxxxii. of the "Medico-Chirurgical Transactions"). Sold by H. K. Lewis, 136, Gower street, London, W.C. 1900. Price 2s 6d. net.

UNQUALIFIED ATTENDANCE UPON HOSPITAL PATIENTS.

AN unfortunate incident occurred at Guy's Hospital on March 14th. An inquest was held upon a baby, aged six weeks, who had been brought to the hospital by the mother who in her evidence said that a young gentleman told her that there was nothing the matter with the patient, but that she had better bring the child next day. During the night, however, the baby died. The student who saw the child gave evidence and said that in his opinion he did not think that there was anything wrong except that the child's skin was red. The house surgeon said that it was the custom for dressers to see patients, but the patients were not informed that the dressers were unqualified. Mr. J. Mulqueen said that death resulted from marasmus and congestion of the left lung. The body was very emaciated. Such a course of events should not be possible. The authorities of Guy's Hospital impose the duty of seeing patients in the surgery upon the house surgeons and assistant house surgeons. The dresser failed in his duty in not calling the attention of the house surgeon to the case and has been severely reprimanded. We see that the coroner's jury added a rider to their verdict that patients should be in every case seen by a medical man and that a record should be kept of the prescriptions given. With the first part of this rider we quite agree—except in the case of a patient who comes in to have a cut finger attended to or, as in a case we knew of, asks to have the nails of his right hand cut—but the second part is impossible so long as the present rush of patients of all classes and kinds continues. We mean by this that if *any other record is to be kept than the* entry on the patient's card or ticket which he or she must preserve a great addition to the staff would have to be made.

ETIOLOGY OF CHOREA.

R. VON KRAFFT-EBING of Vienna[1] has collected 200 cases of chorea, the etiology of which was fairly well ascertained, and found that while 64, or one-third of the cases, were males, 136, or two-thirds, were females. Heredity was distinctly present as a factor, and among other predisposing causes were the changes (in brain and skull) produced by rickets in infancy, and a nervous and irritable constitution. Cranial anomalies were as frequent as in epilepsy, and were in nearly all cases attributable to rickets. Hydrocephalus was relatively common, and in some cases over-exertion and masturbation were found to be contributory causes. In six females out of 136 pregnancy played a causative part. Cerebral concussion was met with as a cause in a few instances. Of the more immediate and exciting causes articular rheumatism and infectious fevers played an important part. Thus in the 200 cases 58 were ascribable to rheumatism, 66 to mental shock, fright, or other trauma, 17 to infectious fevers other than rheumatism, while 59 were due to obscure causes. Shock and fright played a more potent part in patients with a nervous temperament or predisposition, while rheumatic fever seemed to be potent either in the presence or absence of predisposition. Von Krafft-Ebing insists that before the neurotic origin of a case of chorea is accepted an infectious causation should be excluded, and a case is cited in illustration showing that whereas the chorea seemed on inquiry to be of psychic origin—i.e., due to heredity or to mental shock—the post-mortem examination revealed the presence of vegetative or warty endocarditis on the mitral valves, thus showing a rheumatic factor in the origin of the disease.

THE SECOND MALARIA EXPEDITION.

THE Liverpool School of Tropical Medicine has organised a second expedition to West Africa for the study of malaria or, to give the disease its newest name, "gnat fever." The members of the expedition are Dr. H. E. Annett, one of the demonstrators at the Liverpool School (who, it will be remembered, went out with the first expedition) Dr. Elliott of Toronto, and Dr J. E. Dutton, and the party left for Nigeria on March 21st in the *Olenda*. The Colonial Office is giving the party every assistance; a free passage both ways is given by Messrs. Elder, Dempster and Co.; and the African Direct Telegraph Company have also subscribed towards the costs. We shall from time to time publish notes of the proceedings of the expedition. In connexion with this matter we may mention that the Liverpool School of Tropical Medicine has just issued its second memoir. It consists of a report of the malaria expedition of August, 1899, written by members of the expedition, and is copiously illustrated with plates, maps, and micro-photographs. We shall give detailed notice of the work in a future issue.

A VICE PRESIDENT of the Dental Hospital of London, Leicester-square, has presented £100 as a special donation towards the amount urgently required for re-building the hospital with a promise, provided an additional sum of £800 be collected within a reasonable time, that he will give the remaining £100 to complete £1000. The committee are earnestly appealing for contributions to enable them to avail themselves of this generous offer and donations will be gratefully received by the secretary at the hospital or by the bankers, Messrs. Barclay and Co., Limited, 6, Pall Mall East, S.W.

THE course of ten lectures instituted by the late Professor Thomas Dent Mutter, M.D., LL D., on Some Point or Points in Surgical Pathology, will be delivered in the winter of 1902–3 before the College of Physicians of Philadelphia. The appointment is open to the profession at large and the fee is $600. Applications, stating in full the subjects of proposed lectures, must be made before Oct. 1st, 1900, to John H. Brinton, M.D, North-east Corner of Thirteenth and Locust-streets, Philadelphia, Pa., U S A.

DR. W. S. CHURCH, the President of the Royal College of Physicians of London, has become a member of the Athenæum Club under Rule II, which provides for the election by the committee of nine persons yearly who are distinguished in science, letters, arts, or for public services.

IN THE LANCET of Feb. 24th we mentioned the names of various candidates for the Professorship of Medicine in the University of Edinburgh and also intimated that the name of Professor Osler might possibly be added to the list. Professor Osler has, we learn, sent an application for the post.

THE adjourned debate on the Treatment of Rheumatism was continued on Tuesday evening last at the Chelsea

---

[1] Wiener Klinische Wochenschrift, No. 43, 1899.

Clinical Society. Among the speakers were Dr. Pye-Smith, Dr. R. Caton, Dr. Burney Yeo, and Dr. Isambard Owen, while Sir Richard Douglas Powell gave a closing address. We shall publish a full account of the debate next week and hope that there may be some practical outcome of a very voluminous and instructive discussion.

WE are informed that in concluding the winter course of medicine at Glasgow University to-day (Friday) it is Sir William Gairdner's intention to bid farewell to his pupils, as he has decided to resign his position as Professor of Medicine in the University.

THE Midwives Bill Committee of the General Medical Council met on Wednesday last. We presume that it will represent to the Government, which has not yet committed itself to an acceptance of the measure, the omission of its recommendations.

WE regret to learn of the death of Dr. Robert Cory, the Director of the Animal Vaccine Establishment of the Local Government Board and Physician-in-Charge of the Vaccination Department of St. Thomas's Hospital.

DR. H. CAMPBELL THOMSON has been elected to the office of assistant physician at the Middlesex Hospital to fill the vacancy created by the appointment of Dr. W. Pasteur as physician.

THE annual meeting of the Medical Graduates' College and Polyclinic will be held at the College, 22, Chenies-street, Gower-street, W.C., on Wednesday next, March 28th, at 6 P.M.

Dr. HUGH J. M. PLAYFAIR has been appointed Gynæcological Surgeon to the Metropolitan Hospital.

THE DEFECTS OF THE MIDWIVES BILL.

AN ADDRESS BY DR. GLOVER.

AT an ordinary meeting of the Islington Medical Society held on March 20th at the house of Dr. H. F. Stokes, Dr. Glover spoke on the Midwives Bill and the situation now created by the fact that the measure has been read for the second time in the House of Commons. He said:—

You know I have always felt that some legislation on the subject of midwives was inevitable and that the profession could not if it would prevent legislation. There are forces of humanity and forces of social and Parliamentary influence working in this direction which must in the end prevail. From one cause or another there is a considerable section of the female portion of the population which is not attended in confinements by medical men and which is not likely to be. I need not here argue the point. I know there are m union who think that the bulk of the profession does not — The Editors of THE LANCET, who have employers—by concili to get at the roots of this ques- necessary. But there h which disturb the normal harmony of the practitioners who werofession, have found that on action and who by their impatience England and Wales 5000 before the union was sufficiently strong in favour of the Bill, large majority give way and to break their pledges. The n ion of some the patients are miners and trades unionists. Th ly a little rally paid 6*d*. a fortnight and this sum covered Wales, cost of medical attendance for the entire household in ent to case, estimated by Dr. Cox at an average of four persor the hink an average which we imagine must be somewhat below t sla- mark. After conciliatory measures had failed a circular was as sent out in which the colliery surgeons declared that they would cease giving their attendance unless the subscription which I hope will be supplied, but which, I think, if unsupplied, should be fatal to it. While I think midwives must be accepted as a fact in the present stage of civilisation I do not think that medical sanction should be given to any further legal recognition of them except under clear and strong conditions, the chief of which are: firstly, that they shall be severely restricted to ordinary cases and *natural* labours; and secondly, that clear provision shall be made in any Midwives Act for medical help being available for them and the unfortunate patients, whether mother or child, in whose case any abnormality or irregularity arises.

We are all agreed that the high perfection to which midwifery practice has now attained is due to its being incorporated in the art and science of medicine. The more hopeful of us expect that with the growing intelligence and wealth of the people they will be content with nothing less for mothers than the full skill of complete medical practitioners. And meantime we agree to a recognition of the midwife only as a necessity and as one in touch with, and acting subordinately to, the medical practitioner. There are other and minor points in the present Bill requiring amendment. I leave these to others or to another occasion. But I hope to show that this one is urgent and indispensable if medical sanction is to be given to this measure, and I think we have a right to hope that if medical sanction is not given the sanction of Government will be withheld even at the eleventh hour. The Bill had better wait 12 months longer for this completion than be passed without it. It is a life-and-death measure. The lives of women are at stake and of women who have *every claim to our consideration. The Government* have shown by their slow action in this matter their sense of the responsibility of such legislation. They refused to entertain the question seriously till the promoters of it had satisfied the General Medical Council on essential points. Here is a point which the Council thinks "imperative" and it is not expressed in the Bill. It may be said that such power of approval of the regulations of midwives' practice is given to the General Medical Council under the Bill as to secure this point. But I deny that. The General Medical Council is not likely to approve any rules which do not include a requirement that the midwife in case of abnormality or emergency shall apply for medical help. But it has no power to help her to get it or to make such arrangements as shall facilitate her getting it. This must be the work of the local authority which is to license the midwife. I need not remind the society that this is the only condition under which maternity charities are conducted safely; in every district there are medical men appointed to whom the midwife can apply. And I am on strong ground here when I argue that the Bill should contain a clause requiring the local licensing authority to appoint and to pay medical men to whom the midwife is to apply in case of emergency, with power of recovering from persons who are able to pay the medical fee. There are two ways of objecting to this demand. One is to say that in an emergency the parish medical man can be summoned. But this is not a Poor-law business and we do not propose to pauperise those whose case is such as to require a medical practitioner. Another form of objection to a clause securing medical help to the midwife is that such a clause imposes a new expense on local authorities. This seems serious and is probably the explanation of the absence of such a provision in the Bill. But it is not tenable, for the Bill already involves the county council in expense for its general purposes. Remember the legislation is altogether exceptional. It deals with a very special question. It is an attempt to diminish the dangers of parturiency among the poor. The Bill brings women with little training and little knowledge into contact with cases which may suddenly require all the skill and knowledge of a fully-trained medical man. The law is bound to be thorough and not to put the midwife into an impossible position. The objection that such a provision of medical assistance to supplement the work of the midwife will cost the local authority a few pounds a year is trivial and is refuted by the Bill itself, which in two or three clauses makes the county councils answerable for supplying any deficiency in funds required for carrying out the Bill. Clause 5 provides that if the fee, not to exceed a guinea, to be paid for examination and certificate by the midwife is inadequate for the expenses of examination and of the general work of the board, the deficiency shall be supplied from the respective local county funds in proportion to the number of midwives licensed to practice in the said county. Clause 6 empowers county councils to contribute to any deficiency in the funds of the Central Midwives Board So that the pecuniary liability of the county council is already in the Bill. It is only necessary, under Clause 6, to enact that it shall be also liable for any, expenses incurred in procuring necessary medical help for the midwives whom the county council is to license and supervise

I am supported in this view by the fact that it has been pressed by the General Medical Council repeatedly on the Government as a provision of the Bill without which the Council could not support the measure The opponents of this Bill allege its inconsistency with the Medical Acts, which regard midwifery as a part of the medical art and prognosticate danger and death to lying in women. Those who promote it are bound to make it as safe as the system of maternity charities, which has had the sanction of the profession in all ages. With this view I propose that—

I The term "midwife" in the Bill shall mean a woman who undertakes for gain to attend women in *natural* labour

II That a clause be inserted in the Bill requiring the midwife in every case of irregularity or emergency, either of mother or child to *apply for medical assistance*

III That another clause be inserted in the Bill requiring county councils as the local licensing and supervising authority of midwives, to appoint medical men in their districts to whom midwives may refer in cases of emergency, and empowering the county council to recover the costs so incurred in a court of law where the circumstances of the patient are such as to enable her to pay

The above resolutions were carried and it was resolved to forward copies of them to the Members of Parliament for Islington, with a request for their support, and to the Lord President of the Council

THE WAR IN SOUTH AFRICA.

THE hour for the relief of Mafeking is drawing nigh if it has not been already accomplished The nation is justly proud of the brave and spirited conduct displayed by this little garrison and of the pluck and cheery humour of its commander *Without discursing too much into politics* we may say that the longer the war continues the more it has become apparent that it has been mainly brought about through the instrumentality and influence of a relatively small, but very active, portion of the two Republican Governments of South Africa operating upon ignorant, credulous, and misguided peoples The Orange Free State had no cause of quarrel with us and there was no unanimity among the people as a whole in regard to a war from which they had little or nothing to gain even if successful No sooner had the people an opportunity of exercising their free will in the matter than they began to do so, as may be abundantly seen by what has taken place since Lord Roberts reached Bloemfontein

The embarkation of troops for South Africa still goes on apace and the number of arrivals of sick and wounded from that country continues The British and Colonial forces now in South Africa are very large and must soon be so overwhelming as to overcome further resistance, but the march to Pretoria has still to come off and there may still be some severe fighting

The American hospital ship *Maine* has left Durban with a big batch of wounded She is the first ship of the kind to leave the Cape since the relief of Ladysmith, and in addition to a number of officers of different regiments she brings home 153 non commissioned officers and men

With regard to the extent of the permanently disabling effect of gunshot wounds from weapons used in modern warfare we know that the Mauser rifle is on the whole, a humane weapon Mr. Wingfield Digby recently asked a question in the House as to the actual or approximate number of those who had been already cured of their wounds and were back again at duty Mr Powell Williams said that the figures, but *only up to Feb 2nd, were as follows.—Wounded officers*, 261, non-commissioned officers and men, 4583. Returned to duty officers, 67; non commissioned officers and men, 705 These figures do not include casualties in Ladysmith and Kimberley since the investment

Some returns of the sick and wounded among the Boer troops have been published giving higher numbers than have been furnished hitherto, but we regard them as unreliable and below the number of casualties which have actually taken place.

(a) Registrar and secretary and to act as officer commanding the unit till its arrival in South Africa (b) Superintendent or acting superintendent to be selected from the Army Nursing Service in South Africa, an extra nursing sister being included in this detail to allow of the adjustment.

* The P M O Field Force, South Africa, to detail a lieutenant-colonel R.A.M C in South Africa to command this hospital.

Medical Division, War Office, March 21st, 1900

(NOTES FROM SIR WILLIAM MACCORMAC)

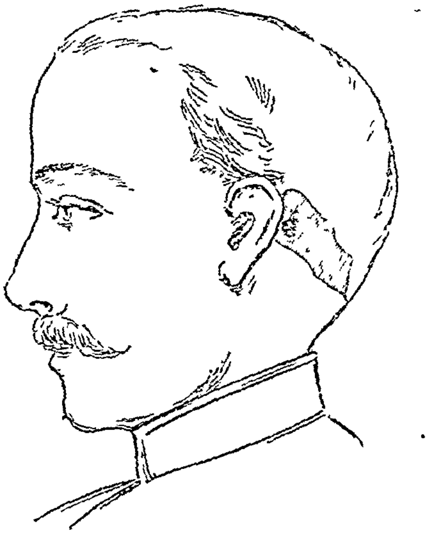
(*Continued from p 797*)

THE following are some further notes by Sir William MacCormac upon interesting cases of gunshot wounds

Wound of the head and the back—Major ——, wounded on Jan 24th at Spion Kop There was a shell wound in the head, five inches long by three at the widest part, extending from behind *the left ear to the middle line of the nape of* the neck The skull was exposed behind the ear at the base of the mastoid process for a circle of the size of a sixpence (see Fig. 1) There was a transverse wound across the back, the entrance was on the left side five and a half inches from the ninth dorsal spine, the emergence on the right was about five inches from the ninth dorsal spine in a quite transverse direction (see Fig 2) The entrance and exit wounds are perfectly circular and are not yet quite healed The officer lost power in his lower limbs for a few days but they have now recovered. There is tenderness over the ninth dorsal spinous process The head wound is granulating healthily and there are no general symptoms. He is now doing well (Feb 14th)

Wound of the head.—Private ——, wounded at Spion Kop on Jan. 24th. The bullet entered two inches externally to the anterior extremity of the sagittal suture on the left side. It was cut out from immediately beneath the scalp in a precisely similar position on the opposite side where it lay beneath the scalp. There is complete motor paralysis of the left upper extremity, but sensation is present. The wounds have healed (Feb. 12th). The patient is otherwise well.

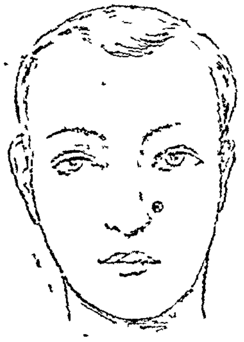
FIG. 1.



The shaved area shows the granulating wound. At the dark spot the bone is exposed.

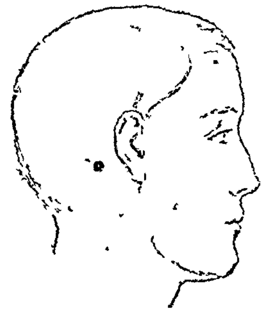
Wound of the head.—Private —— of the 2nd Royal Lancaster Regiment was wounded at Spion Kop on Jan. 24th. The entrance wound was just outside and slightly above the left ala nasi (see Fig. 3), that of exit being half an inch posterior to the tip of the right mastoid process (see Fig. 4). After being wounded there was much bleeding from the nose. At present Feb. 12th) the patient is deaf in the right ear. The wounds have completely healed. He says that he feels perfectly well.

FIG. 3.



Entrance wound.

FIG. 4.

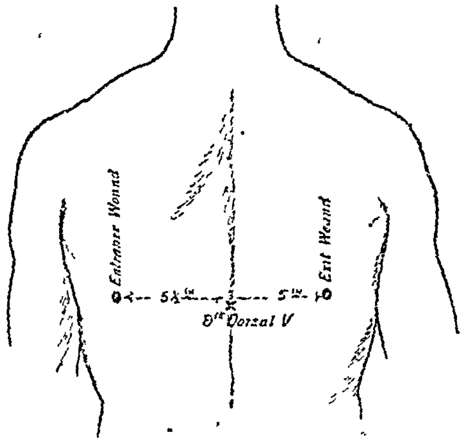


Exit wound.

Wound of the mouth.—Private —— was wounded at Spion Kop on Jan. 24th. The man's mouth was open at the time of the receipt of the injury. The bullet entered the mouth, carried away the whole of the alveolar process and teeth on the right side of the upper jaw, and emerged behind the posterior border of the masseter muscle on the same side The only remarkable point about the case is that complete aphonia set in immediately after the receipt of the injury. This is now, however, disappearing (Feb. 12th).

Wound of the neck.—Private ——, of Thorneycroft's Mounted Infantry, was wounded by a Mauser bullet on Jan. 24th. The bullet entered through the sterno-mastoid muscle on the left side, about two and three-quarter inches above the clavicle, nearly on a level with the pomum Adami, and rather nearer to the posterior than to the anterior border of the muscle (see Fig. 5), and emerged from the centre of the right sterno-mastoid muscle and about an inch above the level of the pomum Adami (see Fig. 6). A considerable amount of external bleeding occurred on the receipt of the wound, but both wounds are now (Feb. 12th) healed. There was at first paralysis of both arms, especially of the left, but the power is gradually and

FIG. 2.

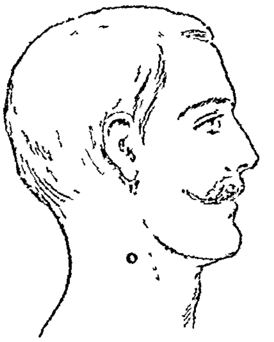


The entrance and exit wounds in the line of the ninth dorsal vertebra.

steadily improving. There is neuralgic pain in the area of distribution of the cervical plexus.

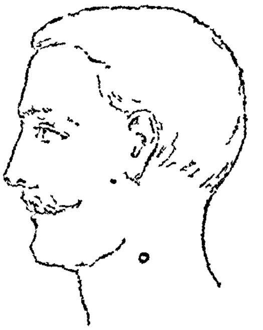
Wound of the arm, damaging the basilic vein, the median nerve, and the brachial artery.—Private —— dropped his service revolver by accident on Jan 24th, which discharged a bullet. This entered one and a half inches directly above the internal condyle of the left humerus and lodged beneath the skin immediately posterior to the tip of the acromion process. The lower two-thirds of the arm were occupied

FIG. 5.



Entrance wound.

FIG. 6.

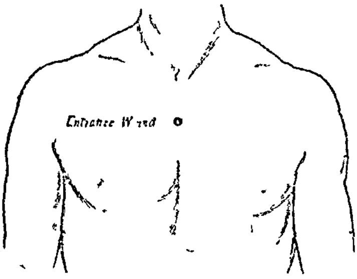


Exit wound.

by an exceedingly tense swelling, causing much enlargement. There was difference of opinion as to whether pulsation could be distinguished in the tumour, but the radial pulse was lost on that side and anæsthesia and paresis in the area of distribution of the median nerve were present. On Feb. 5th a long incision of four inches was made over the course of the artery from the entrance wound upwards, and this was subsequently extended downwards for one inch in the direction of the bend of the elbow. A large amount of coagulated blood was turned out, much of which had apparently passed between the biceps and the brachialis anticus to the outer aspect of the arm. After some dissection the basilic vein, the median nerve, and the brachial artery were exposed. About three-quarters of an inch above the wound of entrance a wound was found in the basilic vein, a slit like perforation (nearly one inch long) in the median nerve, and a large gap in the brachial artery. The vein and the artery were tied above and below the seat of injury The nerve was apparently split very obliquely and four-fifths of its substance appeared to be intact; it was consequently *not interfered with* *Finally, the bullet was extracted*, it was unaltered in shape

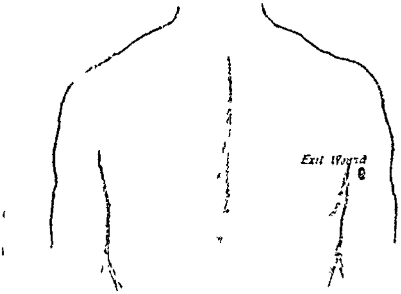
Wound of the thorax —Private —— of the 2nd Middlesex Regiment was wounded at Spion Kop at a range of 800 yards The entrance wound was exactly in the middle line, about two inches below the notch of the sternum, close to the junction of the manubrium with the gladiolus (see Fig 7) The wound of exit was at the posterior aspect of the upper arm, an inch externally to, and on a level with, the point of flexion of the arm upon the thorax (see Fig 8) There was hæmoptysis for two days At present (Feb 12th) there is wrist drop (right), anæsthesia in the area of the ulnar nerve distribution, and great neuralgia in the right arm The wounds have healed How did the great vessels escape?

FIG 7.



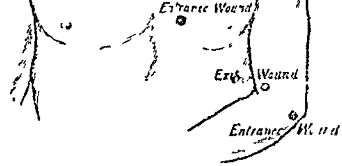
Entrance wound

FIG 8



Exit wound

FIG 10



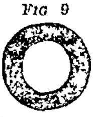
Shows both entrance wounds and first exit wound.

FIG. 11

Shows second exit wound

Wound of the thorax and spine —Captain —— was wounded on Feb 5th at Vaalkrantz The entrance wound was over the ninth rib two and a half inches immediately below the inferior angle of the right scapula, and the exit wound was over the sixth rib in the posterior axillary line on the left side The wounds have completely healed There was complete paraplegia The patient had no control over the bow or bladder Anæsthesia was complete up to the upper thi of each thigh (Feb 12th) There is a bed sore commenci over the sacrum The general condition notwithstanding good

FIG 9



Size of entrance wound

Wound of the thorax —Colonel —— was wounded by shrapnel bullet on Feb 5th The entran wound was behind the left shoulder one inc below the spine of the scapula Tl wound is now (Feb. 12th) scabbed an healed The bullet was removed from subcutaneous position one inch to the rigl of the base of the xiphoid cartilage Th wound has healed. The patient has spa blood, but to a slight extent, since the injur and there are some slight dyspnœa and cougl There are also right wrist-drop and loss of sensation up t the elbow (Feb 12th)

Wound of the lung —Captain —— was wounded o Jan 22nd by a shrapnel bullet from one of our own gun which were captured at Colenso The entrance wound wa over the junction of the outer quarter with the inner three-quarters of the clavicle, immediately beneath the bone which was grooved but apparently not completely fractured The bullet was cut out from beneath the skin on the same evening, three hours after the receipt of the injury, in the field hospital, immediately to the left of the fifth dorsal spine. From the appearance of the bullet and the direction of its track it must have caused partial fracture of the clavicle and possible injury to the ribs and must have traversed the lung. There were slight cough and hæmoptysis for two days with some dyspnœa. Both wounds suppurated freely. The temperature on Feb. 4th was 102° F. On the 5th a small piece of leather (from the patient's belt) came out of the anterior wound. On the 6th the temperature was normal and the patient was much better.

Wound of the lung and the abdomen.—Private —— was wounded on Jan. 24th at an unknown range. The bullet entered at the inner end of the fifth right intercostal space close to the sternum, and it emerged half an inch below the twelfth right rib and two and a half inches from the middle line of the spinal column. There was slight hæmaturia after the receipt of the wound, but there were no other symptoms and the patient is now quite convalescent

Wound of the upper extremity and the thorax.—Private —— was wounded on Jan. 24th at an unknown range. The bullet first entered the base of the left olecranon process and emerged at the inner border of the tendon of the biceps in front at the bend of the elbow (see Fig. 10). It then entered the chest exactly at the level of the left nipple and one and a half inches internally to it and found an exit through the trapezius muscle at the level of the sixth cervical spine and two inches from the middle line (see Fig. 11). There was pain in the chest at night The patient had no cough, but he had a certain amount of hæmoptysis. The wounds have healed (Feb. 12th). It is wonderful how the great chest vessels escaped.

A curious incident occurred in the case of Major ——. This officer was wounded by a Mauser bullet in the thigh. The bullet traversed the thigh transversely and had just sufficient energy to perforate the skin at the exit wound, but could not get through his trousers and so fell down between the thigh and the trousers, being picked out at the knee, where the puttee had prevented its dropping to the ground. The bullet must, of course, have come from a very long range.

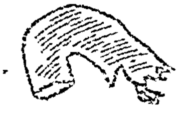
Wound of the abdomen.—Private —— was wounded on Jan. 24th at a range of 500 yards. The wound of entrance was between the eleventh and twelfth ribs vertically above the centre of the left iliac crest. That of exit was through the right os innominatum about two inches below the centre of the crest. There was anæsthesia of the leg below the left knee, but no other symptoms of any sort, although the bullet traversed the abdomen from side to side.

Wound of the abdomen.—Private —— was wounded on Jan. 24th at an unknown range. The bullet entered at the eighth intercostal space in the mid-axillary line on the right side, its point of exit being half an inch above the iliac crest and two inches posterior to the anterior superior iliac spine on the left side. The patient vomited for one hour after the receipt of the injury. He was constipated for three days. His diet consisted of milk for two days and he has had field rations ever since. The bullet must have traversed the liver and probably the bowel also.

Wound of the abdomen.—Private —— was wounded on Jan. 24th at a range of 700 yards. The entrance wound was opposite the tenth dorsal spine and four inches to the right of the median line, while the wound of exit was immediately over the left iliac crest, an inch posterior to its centre. There was slight dyspnœa for three days, since when there have been no symptoms. There is no evidence of any abdominal injury, although it is difficult to suppose that the intestine could have escaped damage.

Wound of the abdomen.—Lieutenant —— was wounded on Feb. 5th by a Mauser bullet. The extracted bullet (Fig 12) was found to be doubled up and damaged, apparently from a ricochet. The entrance wound was of large irregular shape, covered with a scab, about one inch by three-quarters of an inch in size and one and a half inches above the anterior superior spine of the right ilium. The bullet was cut out on the day after the receipt of the wound from the centre of the right buttock. This wound is quite healed. There were no symptoms.

FIG. 12.



Extracted bullet.

Wound of the abdomen.—Private —— was wounded at Spion Kop on Jan. 24th The bullet passed through the left wrist while the man was sitting up drinking. It then entered the abdomen exactly in the middle line, one and a half inches above the umbilicus, in a direction somewhat sloping to the right side. There is no wound of exit. There is difficulty in defecating and in micturating with much straining at stool, but no blood has passed either in the fæces or in the urine. There is considerable abdominal distention (Feb. 11th). No rise of temperature. The wounds have healed and the symptoms are improving.

Wound of the thigh (involving the common femoral artery).—Private —— was wounded on Jan. 24th at a range of 600 yards. The entrance wound was exactly over the common femoral artery, one and a quarter inches below Poupart's ligament. The bullet crossed close to the anterior surface of the femur three quarters of an inch below the tip of the trochanter major. There is a pulsating swelling in the line of the artery with a marked thrill and loud bruit as if there was a communication between the artery and vein. On Feb. 6th an incision was made extending from about an inch above Poupart's ligament downwards for five inches along the course of the artery. The tissues were found to be much matted together by inflammatory material and after some dissection a gush of blood disclosed the situation of the wounded vessel. The forefinger of one of the assistants being placed in the aperture arrested the bleeding. The common femoral artery, after a troublesome dissection, was exposed above and the superficial femoral artery below the opening and they were ligatured, but the bleeding still continued. It was then found that the vein had also been lacerated. This was isolated above and below and ligatured in two places, but still the hæmorrhage continued immediately the finger was removed—apparently from the profunda artery—the main vessel having been traversed just where that trunk is given off. After considerable difficulty this also was secured. Mr. Hulke performed the operation and I and others assisted him. There was no extravasated blood or clot found throughout the operation though the wound in the vessel was as large as the end of the forefinger, which is sufficiently remarkable, and there was no evidence of backward pressure in the vein although the opening in the vein and artery appeared to communicate. This man subsequently died.

Wound of the thigh involving the femoral artery and vein.—Private —— was wounded on Jan. 21st at an unknown range. The entrance wound was exactly at the middle of the posterior aspect of the right thigh, and the exit wound was at the junction of the lower and middle thirds of the same thigh, on the inner side, in the line of the femoral artery. There was increased pulsation with some swelling which involved the area of the exit wound. There was no bruit. Pulsation was to be felt in the dorsalis pedis and posterior tibial arteries. An operation was performed on Jan. 29th. An incision about six inches in length was made over the course of the artery, the exit wound being a little below the centre. On laying open Hunter's canal there appeared to be no extravasated blood or clot, but considerable hæmorrhage took place from a wound half an inch in length on the anterior aspect of the artery and in its long axis. The aperture in the vessel was of irregular shape and was situated an inch above the opening in the adductor magnus. The hæmorrhage was arrested by pressure in the wound and the artery was isolated above and below and ligatured. The skin wound was then sutured. The temperature on the night of the operation was 101° F., but it fell to normal on the next morning and has remained so ever since. On Feb. 6th (the first time of dressing the wound) the stitches were removed. There was a little sanious discharge but the wound had completely healed, with the exception of about one inch in the vicinity of the exit wound. The collateral circulation in the limb has been fully established and the patient is otherwise quite convalescent. It is remarkable that in this as in several other instances there should be little or no bleeding into the tissues from a large wound in a large artery.

The injuries here noted were received about the same time (Jan 24th) and their condition is described on Feb. 5th and 12th. The men were mainly all convalescent and most of the wounds had healed under a scab. With the exception of the case of injury to the brachial artery and median nerve the cases of abdominal injury and the chest injuries are further instances of the extraordinary recoveries which follow damage of this nature inflicted by the Mauser bullet. It is curious also, as in two other similar cases, that the Mauser bullet can split a nerve of the size of the median nerve without severing it.

Another remarkable feature is absence of extravasation in the case of the wound of the common femoral artery and profunda artery, and the same was the case in the injury implicating the femoral artery in Hunter's canal. How in one case the vessels at the root of the lungs and in another those arising from the arch of the aorta escaped is nothing short of an anatomical puzzle.

These cases are selected from amongst many in the hospital at Mooi river which is doing most excellent work under the direction of Colonel J. A. Clery, R.A.M.C. The succession of cases from the front has been almost daily during the past weeks and the proportion of serious cases amongst them is very large. WILLIAM MACCORMAC

(FROM OUR SPECIAL CORRESPONDENT AT THE BASE.)

This morning news that Cronje was a prisoner in Lord Roberts's camp, though of course stale to you by this time, has been received by everyone here with feelings of intense satisfaction and has, I am sure, acted a great deal better than all our "tonics" to the majority of the sick and wounded at present filling the hospitals. As regards my own charges I can only say I had great difficulty in restraining them all, amputation cases included, from demanding their immediate discharge in order to proceed at once to the front! At the same time our successes are tempered with a terrible list of casualties and the wounded and sick are pouring down from all parts of the front, the trains following each other at very short intervals. The numbers in Hospitals No. 1 and No. 2 to day are roughly:—No. 1: Officers, 73; non-commissioned officers and men, 560. No. 2: Officers, *nil*, non-commissioned officers and men, 580; and Boer prisoners wounded, 32. No. 3 ambulance train arrived yesterday from Kimberley with 31 sick and wounded officers and 83 non-commissioned officers and men. The most serious cases are being left at the hospital in Kimberley on this side and at Pietermaritzburg in Natal. Of course, a great number of these cases are medical, principally dysentery, sunstroke, and enteric fever, it being the object to clear out the hospitals at the front as much as possible. Everything is working very smoothly and the foresight of the Surgeon General in establishing a sanatorium for sick and wounded officers is relieving the overcrowded state which would necessarily ensue in the base hospitals had there been no means of passing slight cases on. Of course, the present rush of wounded and sick is taxing our resources to a great extent, but luckily there are plenty of transports in the harbour and we are filling them up as far as we can; a great number of nursing sisters and civilian lady nurses have been ordered to Natal on short notice as I hear that there are nearly 3000 sick and wounded who will require nursing immediately Ladysmith is relieved, a matter I suppose of hours now—at least, we hope so. There is, I am happy to say, no lack of material and the civil population are vieing with each other in offers of assistance. Several more officers of the Royal Army Medical Corps and civil surgeons have gone up to Kimberley and the surrounding country, and there is a big base hospital of 500 beds at Naupoort. Sir William MacCormac and Mr. Makins are here and the other consulting surgeons are scattered about the front where their services are mostly required. I am sorry to say there have been several deaths from dysentery amongst officers and men, no doubt due to bad water, and the type of disease has been a very severe one, resembling as regards post mortem appearances the Indian scourge in all its worst forms. Enteric fever as far as I can ascertain has not been so fatal as we were at one time led to suppose, but it has been bad enough in all conscience, and I am afraid that we shall hear some terrible tidings of the ravages of the disease when we get into Ladysmith, which place on all hands is condemned utterly as a military station in the future. As regards the safeguard of inoculation I am not at present in a position to give any very definite opinion, but from the few cases I have seen down here I am satisfied that inoculation has undoubtedly mitigated the symptoms and lessened the mortality, yet I think it full early to give a positive opinion on its merits as a preventive. I am struck much by the marvellous effect of this climate, during the summer months at least, on chest cases. I have seen several undoubted cases of tubercle, or commencing tubercle, of the lungs simply lose every characteristic symptom after a few months' open-air treatment in this climate and to all intents and purposes recover. Whether a return to other climates will light up the old mischief or not remains to be seen, but I am at present keeping my eye on a case in which when I first saw the patient about the middle of December, I considered the gravest prognosis the only one allowable; however, the patient, after battling with a varying temperature of over 100° and frequently running up to 103° at night, with night sweats, emaciation, persistent cough, and every symptom, including bacilli in the sputum, has improved to the extent that he is able to take a fair amount of exercise, feels fit, and is clamouring to be sent to the front. The same remarks apply, as far as climate goes, to patients suffering from nervous exhaustion, dysentery, and sunstroke, who come down perfect wrecks and in a few days, after a residence at Claremont, pick up in a marvellous manner and are fit for duty again. Its curative powers on gunshot wounds I have already described in my earlier letters, and I can now, after a residence here of over four months, endorse every word I then said; in fact, during the spring and summer Cape Town, or rather Wynberg and Claremont, are, as regards climate, simply perfect places for the sick and wounded. We are well off now in the matter of hospitals, as there are several more, including the Yeomanry, to be established in the neighbourhood of Cape Town, so that no misgivings regarding accommodation need be felt.

Wynberg, Feb. 28th.

THE ROYAL COMMISSION ON THE METROPOLITAN WATER-SUPPLY.

(Concluded from p. 798.)

THE Commissioners proceed to consider what amount of flow in the Thames ought to be maintained. Sir Alexander Binnie contended that the flow over Teddington Weir ought never to be reduced to less than 250,000,000 gallons a day and that the river would silt up below Richmond if the flow were materially reduced below that figure. The Thames Conservators passed a resolution in the year 1892 and again in 1896 insisting that after the water companies had taken 130,000,000 gallons daily from the Thames they ought not to be allowed to increase this amount unless the day's discharge at Teddington Weir exceeded 200,000,000 gallons, and then the excess only ought to be taken, so that the discharge over the weir would not fall below 200,000,000 gallons. Sir Frederick Dixon-Hartland, chairman of the Thames Conservancy, objected to the daily flow over Teddington Weir ever being reduced to less than 200,000,000 gallons. The Commissioners are of opinion that the minimum flow over Teddington Weir should be fixed at 200,000,000 gallons and that the companies should not be allowed to deplete the river so as to reduce the flow below that amount "except under special safeguards and restrictions." At the present time the companies have a statutory right to draw 130,000,000 gallons from the Thames without reference to the effect this draught may have on the discharge at Teddington. Of this statutory right they could not be deprived "without their consent or without consideration." Their consent might well be given if they were granted the privilege of drawing their daily quota, not in each 24 hours, but on an average of six months. In that case the companies would not draw water when the river was low and the whole of the water was wanted to keep up the necessary flow over Teddington Weir and "this would be advantageous in the public interest." A material consideration in estimating the cost and possibility that a supply from the Thames could be obtained in sufficient amount to last up to 1941 is the question as to whether the companies should be allowed to draw flood-water into their reservoirs or whether they should be restricted from taking water at the height of the flood. On this question the Commissioners think that discretion may be left to the engineers of the companies and that it may be assumed that as turbid water is a trouble and expense they will when practicable allow a few days of flood to go before they draw the water and therefore a prohibition against the taking of flood-water is unnecessary. To ensure a flow of 200,000,000 gallons a day over Teddington Weir would only be possible by greatly increasing the capacity of the storage reservoirs provided. As to the cost which these reservoirs would entail the Commissioners received conflicting estimates from Sir Alexander Binnie, Mr Middleton, Mr. Hunter, Mr. Hawksley, and others. They do not discuss the details of the estimates, but with the assistance of Colonel Rathbone, who was employed as assistant Commissioner, they estimate that the cost of supplying sufficient storage to supply Water London from the Thames with 114,500,000 gallons a day in addition to the 185,500,000 gallons a day (which the companies and the Staines Reservoirs Committee are now authorised to take) in a year as dry as 1893 will be between £9,000,000 and £10,000,000. This estimate, however, does not cover the cost which would be incurred if the existing authorised draught of the companies and of the Staines Reservoirs Committee—namely, 185,500,000 gallons a day—were made subject to the condition that water shall not be taken from the Thames so as to reduce the flow over Teddington Weir below 200,000,000 gallons a day. If this were done by an alteration in the statutory rights of the companies and with their consent the cost of supplying a sufficient storage and pumping power would be £2,800,000 and £2,000,000 further expenditure would be necessary for connexion with the systems of the different companies. The cost of this outlay for making arrangements for the abstraction of more water from the Thames would be gradually incurred and the reservoirs would be made as the need for them arose, so that if the population did not increase at the expected rate the works might be delayed. The works which would be done would become remunerative and productive of income as soon as they were finished. The Commissioners remark that there are other less costly sources of supply, that 27,500,000 gallons a day could be taken from wells in Kent, and Lord Balfour's Commission reported that water might possibly be obtained from chalk wells in the Thames basins above and below the companies' intakes and that wells in the Lee valley might be expected to produce 40,000,000 gallons in dry years and in wet years 58,000,000 gallons or more daily.

The general conclusion to which the Commissioners come is that the estimate that 120,000,000 gallons a day from the Lee and springs and wells of the Lee valley and Kent is not an over-estimate, and that an additional supply from the chalk in Kent and from the Thames valley might be obtained to supplement the supply of 300,000,000 gallons a day from the Thames for the needs of London up to the year 1941. The Commissioners report that much of their time was occupied in considering the scheme for getting a supply from Wales. Estimates differing very greatly in amount were given by witnesses as to the cost of the proposed undertaking, and the divergencies of the estimates were so great "as to make the task of deciding between them difficult and hazardous." The Commissioners think that there is something attractive in the scheme for bringing water from the Welsh mountains for the supply of London and "one would be glad if it were possible now to secure a watershed to be used hereafter if London should require it." The Commissioners report, however, that no chemical or bacteriological tests with regard to the quality of the Welsh water are in evidence, but that it had been stated that the water was free from microbes and contained practically the same organic elements as the London water, and that some of the water was said to be of exceptional purity and softness and might dissolve a considerable portion of lead and this Professor Dewar warned them would probably necessitate proper treatment before it could safely be used. The Commissioners received no statistics with regard to the effects of the drought in the years 1893 and 1898 and the amount of average rainfall was estimated in the driest years to be 80 of the average rainfall. Should the present supplies prove sufficient in quantity and of satisfactory quality it seems unnecessary that the cost should be incurred of bringing water from a distance to London.

The cost of constructing works near the Thames is not the only expense which will have to be borne by the companies or by a purchaser between the present time and the year 1941. Much will have to be expended in making storage works in the Lee valley, for the machinery necessary to utilise further supplies from the chalk, and in laying mains for the distribution of water. The Commissioners estimate that the total capital expenditure up to the year 1941, should the Thames and other local supplies be used, will amount in round figures to £18,100,000. This expenditure will have to be made whether additional supplies are obtained from the Thames or from Wales, or from other sources, but as it will be incurred for supplying new customers it will bring an immediate increase to the income derived from the water rates.

The estimate given by the Commissioners exceeds that given by the companies. In pointing out this fact the Commissioners say that they addressed a circular to the directors asking them for an estimate of what they expected their capital expenses would amount to during the next 40 years. The estimates amounted altogether to a sum of £13,720,150, but the directors and their engineers expressed their sense of the difficulty they had in giving definite figures, and this difficulty they thought so great that they felt it impossible to ensure anything like accuracy. The Commissioners in summing up their own figures estimate that the capital expenditure required up to 1941 will be £4,800,000 to bring a daily supply of 185,500,000 gallons, which is the present authorised draught from the Thames, if the conditions of storage and river flow which they recommend are provided for. To provide adequate storage for an additional supply of 114,500,000 gallons from the Thames the cost will be £9,000,000 or £10,000,000; for works of distribution £18,100,000; for storage works on the Lee a further amount (not specified) must be added to the total of £32,000,000 to £33,000,000. Should further supplies be obtained from Wales the outlay would be much increased. The magnitude of the future requirements of London in regard to water-supply lead the Commissioners to the conclusion that the concentration of the water undertakings into the hands of one authority is desirable. It will be necessary to make large works should the supply be taken from the Thames and the Lee without injury to the rivers. There will be practical difficulties in carrying out these works if the undertakings are not owned by a single authority. The amalgamation of the existing companies according to one witness would be extremely difficult, according to another impracticable. A public authority would be able to raise the necessary sum for carrying out new works at a cheaper rate than the companies could obtain it if the authority had power to borrow on the security of the general rates, and in that case money might be raised at from ¼ to ½ per cent. less than the companies would have to pay. The whole expenditure mentioned will not have to be made immediately, but it is likely to be less remunerative than similar expenditure made by the companies has hitherto been and the new supplies required will be more expensive. The companies have been working on a tide of prosperity and, as a rule, their profits have steadily increased. The Commissioners ask themselves what would happen if there were a necessity for large expenditure which would probably be unremunerative for some time with the consequence of reduced profits to the companies, and they answer their question by saying that the directors, having before them the double duty of safeguarding the interests of the shareholders and of the consumers, would be placed in a difficult position which might lead to results unsatisfactory to the consumers, whereas a public authority having acquired the undertakings would be likely to have no other object in view than to satisfy the requirements of the consumers. Having regard, therefore, to the future requirements of Water London it is desirable that the undertakings should be acquired and managed by a public authority. If after purchase by a public authority a sinking fund were dispensed with and the present water charges were maintained the purchaser might be able to pay his way and the increase of the water revenue might make it possible to reduce the charges for water sooner than such a reduction would be made under the management of the companies, because in the latter case the maximum dividends would have to be reached and the payment of back dividends must take place first. The reduction would also extend to the New River district, on which no reduction is obligatory so long as this company exists with its present statutory rights.[1]

The Commissioners having come to the conclusion that the water companies' undertakings should be bought by a public authority proceed to consider by what authority the purchase should, in their opinion, be effected. They give a summary of the sources of the water supplied by the companies and then refer to the evidence of Sir Alexander Binnie with regard to division of the sources of supply between the metropolitan counties and London, pointing out that schemes of severance would result in the London County Council being made the water authority for part of the county and not for the rest and would lead to complications with the independent suburban water companies and local authorities which supply water and which exist to the number of 18 in Greater London or the parts of Water London outside Greater London. Sir Alexander Binnie thought that the metropolitan councils would find themselves driven to take water in bulk from the London County Council. The difficulties attending this course have been already stated, and the representatives of the metropolitan counties, moreover, insist on being severed from London both with regard to the supply and to the distribution of water in case of the purchase of the present undertakings by the London County Council. The difficulties which have been pointed out having led the Commissioners to advise that the London County Council should not be the purchaser, they proceed to report as to what authority if the policy of purchase be adopted should acquire the undertakings. It is not desirable that several authorities should become the purchaser. Any advantage which might obtain from the purchase, whether financial or administrative, will arise only from amalgamation of the sources of supply and distribution so that they may be used economically and with a view to the needs of every part of Water London. The feeling against purchase by a Water Board formed on the basis of population and rateable value is emphasised by the metropolitan counties on several grounds, and the practical difficulty of creating any water trust based on strictly representative principles was shown by the history of a Government Water Bill introduced in the year 1896, which, owing to the opposition of the metropolitan counties, was so modified in Parliament that a clause enabling any county to take itself out of the water trust was inserted and the Bill was dropped. The Commissioners appreciate the great difficulty in advising as to the constitution of a Water Board which will be accepted by the various interests concerned and by Parliament, but considering the importance and intricacy of questions relating to future water-supply, the large amount of works which will have to be undertaken, the difficulty of obtaining from eight separate companies that unity of action which is necessary for bringing such works to a successful issue, the importance of bringing about absolute coalescence of the water companies' undertakings,—all these things lead to the conclusion that the purchase and management by a single public authority will solve the question satisfactorily. The suggestions which are made with regard to the constitution of a water authority which should undertake these vast duties are as follows: the Water Board should be a permanent body consisting of not more than 30 members; its proceedings should be brought under the observation of Parliament automatically and periodically; and it should include delegates from the Local Government Board. The suggested composition is that the London County Council should appoint 10 members, the Conservators of the Thames four members, the County Councils of Middlesex, Surrey, Essex, Hertford, and Kent, the Lee Conservancy Board, and the Common Council of the Borough of West Ham two members each. The chairman and vice-chairman should be appointed by the Local Government Board. The appointing authorities should be empowered to fill any vacancy caused by the death or the resignation of a representative. The offices should be held for a definite (unspecified) number of years. The chairman and vice-chairman should receive adequate salaries. The other members of the board should be paid according to their attendances (as is now done in the case of the Conservators of the river Thames). The board should be required to acquire the undertakings of the metropolitan water companies by agreement or by arbitration. The boroughs of Croydon and Richmond are reasonably entitled, if they wish it, to be made independent of the board. The board should be entitled to issue 3 per cent. stock secured on the water charges of the whole area; this should be made a trustee investment transferable at the Bank of England. The Chamberlain of the City of London should transfer all the money which has accumulated as the result of the sinking fund clauses, and these clauses should be repealed at and from the date of purchase of the undertakings. The price of purchase should be payable in cash at the option of either the vendors or the purchasers. The vendors may be paid in the stock of the board should the shareholders agree to that course. Should a sinking fund be required the probability of a deficit will arise and this will make it necessary to empower the Board to increase the water charges which the companies are entitled to demand if the interest on the stock cannot be otherwise paid. In any case the Commissioners think such a precaution would be a prudent one. It would not be unreasonable to empower the board in case of deficit to levy a rate in aid. A rate in aid supplements the insufficiency of charges and is unjust to those ratepayers who have provided themselves with a water-supply and take nothing from the companies as in the case of breweries and other industrial establishments: but there are public purposes, such as extinguishing fires, street-watering, the supplies for public baths, &c., which benefit all ratepayers whether they take water or not, and in consideration of them all ratepayers may be called upon to make some contribution for the services rendered. Possibly the Water Board would have occasion to look to the rates for further assistance. It is this possibility which arouses the fears and excites the opposition of counties such as Middlesex and Kent. The Commissioners make a suggestion by which this opposition "may be quieted." Assuming, they say, that the Water Board has to borrow £10,000,000 at an annual charge, say of £300,000, for interest, if that charge were distributed among the six counties concerned in the proportion of the number of supplies they are respectively taking, the contribution asked from time to time will be roughly proportioned to their own needs and not to the needs of other counties The Commissioners suggest that the contribution should be demanded by precept issued by the Water Board to the county authorities when the money would be raised by the local authorities either by an equal rate or by rates levied in the parishes affected in the proportion of the number of water supplies given.

---

[1] At the present time the New River Company does not charge the full rates which are authorised.

As to whether it would be better to enable the proposed Water Board to meet deficiencies of revenue by recourse to the rates or by making an increase in the water charges is "a question of policy" which the Commissioners decide it is not for them to determine, and they content themselves by emphasising the possibility or probability that such deficiencies will arise should the proposed Water Board come into being on the lines suggested, and by pointing out alternative means of raising the money which is likely to be or may be wanted. The Water Board should be required to draw up an annual report of the statement of accounts. This should be audited by an independent auditor. The report and the account should be included in the annual report of the Local Government Board.

LEAD POISONING IN THE POTTERY DISTRICTS.

AT a meeting summoned by the Duchess of Sutherland at Trentham on Wednesday, March 14th, a conference of the medical men of the neighbourhood took place to consider the most thorough treatment of the cases of lead poisoning which occur in the Pottery districts. Dr. H. Lewis Jones of the Electrical Department of St. Bartholomew's Hospital, London, had been invited to speak on the electrical treatment of these cases from his experience of those patients sent from the Potteries to be under his care. The chair was taken by Dr. A. M. MCALDOWIE and the meeting was well attended, over 40 persons being present. In speaking of electricity in the treatment of paralysis due to lead poisoning Dr. LEWIS JONES said that cases of lead poisoning were not particularly common in London, about a dozen cases a year applying for treatment at the electrical department of St. Bartholomew's Hospital, and the type of case seemed to differ from that sent from the Pottery districts in that the patients were older and had the disease in a more chronic form. The interesting points about the cases from the Potteries were the comparative youth of the patients and the severity of their paralytic symptoms, which though more serious were more amenable to treatment by reason of the fact that the intoxication by the lead had gone on for a shorter time With regard to the mode of treatment, ten years ago it was by the direct application of the constant current to the paralysed muscles by means of hand electrodes; from that it had been changed to treatment by means of electrical arm-baths; the current employed had also been changed from the constant current to the induction coil with arm-bath and later to the current from the mains With the present mode of application patients seemed to improve rather more rapidly. It was difficult in all matters concerning efficacy of treatment to bring forward absolute and conclusive evidence that recovery was due to the treatment applied, but this could be said, that on the commencement of electrical treatment improvement began for the most part immediately and the progress of improvement coincided very closely with the progress of the treatment. Wrist-drop from lead was a serious condition and was slow to yield to any treatment. It was often necessary to persevere with it for from three to six months or even longer before the full benefit could be secured by the electricity. Because of this there was a tendency to regard electrical treatment as of little or no use and to think that any improvement which might take place was due to lapse of time or to natural causes. In trying to estimate the value of electrical treatment there was the difficulty of understanding exactly how the electricity worked. The question of the elimination of metals in various kinds of metallic poisoning was an old one. Electric baths had been recommended for the extraction of lead, mercury, and other metals from patients' bodies, but these metals tended to natural and spontaneous elimination in the ordinary course of events; the rate of elimination could be promoted or retarded by drugs, but the treatment of the paralysis and the elimination of the metal were independent of each other in so far as the one could be measured by the other, and it was very difficult to prove that lead could be extracted from a patient's body by processes of electrolysis. Alternating currents were almost invariably used in the treatment of lead poisoning at St. Bartholomew's Hospital, therefore it was clear that electrolysis played no part in the recovery of such cases because electrolysis was a property of the direct current. The electricity acted as a stimulant to the nerves and muscles involved and to the blood-supply circulated through them, and by stimulating these parts the natural process of elimination was also stimulated. The routine method of treating wrist-drop caused by lead was as follows: an arm-bath of stoneware was filled with warm water and the forearms and hands of a patient were immersed in it and a current was passed from one end of the bath to the other through the water and the limb between two electrodes placed at the ends of the bath. The alternating current was used in preference and the 100 volts from the electric light mains were reduced by a transformer to 12, 14, or 16 volts to suit the cases. It was, perhaps, unusual to find an alternating current advocated for treating muscles which showed the reaction of degeneration and which were unable to respond by contraction to rapidly alternating currents. But this was part of a large question. Experience had shown over and over again that alternating currents had a valuable influence upon muscles which did not contract to them. For the treatment of the paralytic form of lead-poisoning electricity was undoubtedly the best, and for conditions other than paralysis, particularly the anæmia and debility which were often met with, electricity again rendered important service in assisting the natural elimination of the poison and promoting the general activity of the tissues. To render electricity a practical method it was necessary to make it easy of application. The arm-bath with an induction coil represented the simplest electrical application possible and reduced the labour of treating a patient to a minimum.—Dr. R. ALCOCK, Mr. W. ARMSTRONG, Dr. W. C. D. PRENDERGAST, and Mr. F. F. ARMYTAGE also spoke, and the last-named gentleman showed three cases.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6659 births and 4525 deaths were registered during the week ending March 17th. The annual rate of mortality in these towns, which had declined from 25·8 to 20·4 per 1000 in the four preceding weeks, further decreased to 20·3 last week. In London the rate was 18·8 per 1000, while it averaged 21·3 in the 32 provincial towns. The lowest death-rates in these towns were 12·7 in Croydon, 14·9 in West Ham, 16·4 in Brighton, and 16·5 in Bristol; the highest rates were 25·7 Salford, 27·6 in Liverpool, 28·6 in Oldham, and 31·1 in Preston. The 4525 deaths in these towns included 423 which were referred to the principal zymotic diseases, against 416 and 424 in the two preceding weeks; of these, 141 resulted from measles, 124 from whooping-cough, 77 from diphtheria, 32 from "fever" (principally enteric), 28 from diarrhœa, 20 from scarlet fever, and one from small-pox. No fatal case of any of these diseases occurred last week either in Swansea, Birkenhead, or Huddersfield; in the other towns they caused the lowest death-rates in Croydon, Nottingham, and Sunderland, and the highest rates in Plymouth, Wolverhampton, Salford, and Preston. The greatest proportional mortality from measles occurred in Plymouth, Cardiff, Wolverhampton, Salford, Preston, and Halifax; and from whooping cough in West Ham, Wolverhampton, *Birmingham, Liverpool, Leeds*, and *Newcastle*. The mortality from scarlet fever and from "fever" showed no marked excess in any of the 33 towns. The 77 deaths from diphtheria included 35 in London, eight in Sheffield, seven in Leicester, five in Leeds, and four in Bristol. One fatal case of small-pox was registered last week in Cardiff, but not one in any other of the 33 large towns. There were five cases of small-pox under treatment in the Metropolitan Asylums Hospitals on Saturday, March 17th, against seven at the end of the two preceding weeks; two new cases were admitted during the week, against three, two, and one in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 1760, against numbers decreasing from 3578 to 1777 on the 17 preceding Saturdays; 181 new cases were admitted during the week, against 160, 154, and 147 in the three preceding weeks. Influenza was certified as the primary cause of 26 deaths in London. The deaths referred to diseases of the respiratory organs in London, which had declined from 527 to 378 in the four preceding weeks, rose again to 391 last week, but were 130 below the average. The causes of 64, or 1·4 per cent., of the deaths in the 33 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Nottingham, Leeds, and in 10 other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Liverpool, Preston, Hull, and Newcastle.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 31·7, 29·0, and 27·7 per 1000 in the three preceding weeks, further declined to 22·7 during the week ending March 17th, but exceeded by 2·4 per 1000 the mean rate during the same period in the 33 large English towns. The rates in the eight Scotch towns ranged from 15·9 in Leith and 18·6 in Dundee to 26·6 in Greenock and 27·0 in Perth. The 700 deaths in these towns included 18 which were referred to diarrhœa, 17 to measles, 15 to whooping-cough, five to scarlet fever, four to diphtheria, and four to "fever." In all 63 deaths resulted from these principal zymotic diseases, against 69, 74, and 92 in the three preceding weeks. These 63 deaths were equal to an annual rate of 2·0 per 1000, which was slightly above the mean rate last week from the same diseases in the 33 large English towns. The fatal cases of diarrhœa, which had been 18 and 25 in the two preceding weeks, declined again to 18 last week, and included five in Edinburgh, five in Aberdeen, three in Glasgow, and three in Dundee. The deaths from measles, which had been 20 and 17 in the two preceding weeks, were again 17 last week, of which seven occurred in Glasgow, five in Dundee, and four in Paisley. The fatal cases of whooping-cough, which had been 15 and 24 in the two preceding weeks, declined again to 15 last week, and included five in Glasgow, five in Edinburgh, and two in Perth. The deaths from scarlet fever, which had been 10 in each of the two preceding weeks, declined last week to five, of which three were registered in Glasgow. The four fatal cases of diphtheria showed a decline of three from the number in the preceding week and included two in Glasgow. The deaths referred to different forms of "fever," which had been six and nine in the two preceding weeks, declined again last week to four, of which three occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 362, 324, and 259 in the three preceding weeks, further declined to 189 last week, but showed an excess of 51 over the number in the corresponding period of last year. The causes of 27, or nearly 4 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 34·3 and

36·8 per 1000 in the two preceding weeks, declined again to 31·2 during the week ending March 17th. During the past four weeks the death-rate in the city has averaged 38·3 per 1000, the rate during the same period being 19·5 in London and 22·6 in Edinburgh. The 209 deaths registered in Dublin during the week under notice showed a decline of 33 from the number in the preceding week, and included nine which were referred to the principal zymotic diseases, against 12 and 10 in the two preceding weeks; of these four resulted from measles, four from diarrhœa, one from whooping-cough, and not one either from small-pox, from scarlet fever, from diphtheria, or from "fever." These nine deaths were equal to an annual rate of 1·3 per 1000, the zymotic death-rate during the same period being 1·7 in London and 2·2 in Edinburgh. The fatal cases of measles, which had been five, one, and two in the three preceding weeks, further rose last week to four. The deaths from diarrhœa, which had been five and three in the two preceding weeks, rose again to four last week. The 209 deaths registered in Dublin last week included 34 of infants under one year of age and 58 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a slight decline from the numbers recorded in the preceding week. Seven inquest cases and four deaths from violence were registered, and 78, or more than a third, of the deaths occurred in public institutions. The causes of 17, or more than 8 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Surgeons: A. H. Prichard to the *Research*; J. N. Robertson to the *Triton*; A. W. B. Livesay and J. P. Willis to the *Pembroke*, for Chatham Dockyard; H. R. Gardner to the *Thunderer*; and R. J. Mackeown to the *Excellent*.

THE IMPERIAL YEOMANRY.

Thomas Walcot to be Medical Officer, with the temporary rank of Captain.

ROYAL ARMY MEDICAL CORPS.

Surgeon-Captain A. Macdonald, A.M.R., assumes medical charge of troops, Station Hospital, &c., Edinburgh Castle. Lieutenant-Colonel R. Drury assumes medical charge of the Female Hospital, staff, and departments, Curragh Camp. Brigade-Surgeon-Lieutenant-Colonel F. Howard, A.M.S., (retired) and Captain W. H. P. Lewis join the Home District for duty.

Surgeon-Major E. J. Lawless, 4th Volunteer Battalion the East Surrey Regiment, is granted the temporary rank of Major whilst serving in South Africa. Surgeon-Lieutenant John K. Tomory, 1st Sutherland Volunteer Corps, is granted the temporary rank of Lieutenant whilst serving in South Africa. Captain C. F. Wanhill, from the Seconded List, to be Captain, vice R. H. E. G. Holt, who died from wounds received in action. Surgeon-Major E. L. Freer, 1st Volunteer Battalion the Royal Warwickshire Regiment, is granted the temporary rank of Major whilst serving in South Africa. The undermentioned officers are granted the temporary rank of Lieutenant while serving in South Africa:—Surgeon-Lieutenant A. H. McDougall, 1st Volunteer Battalion the Royal Warwickshire Regiment; Surgeon-Lieutenant John Clay, 2nd Volunteer Battalion the Northumberland Fusiliers.

VOLUNTEER CORPS.

6th Lancashire: Surgeon-Major J. B. Oliver resigns his commission, with permission to retain his rank and to wear the uniform of the corps on his retirement. 2nd Middlesex: Ernest Alfred Snape to be Surgeon-Lieutenant. 1st Volunteer Battalion the Cheshire Regiment: Surgeon-Lieutenant C. T. Green to be Surgeon-Captain. 2nd Volunteer Battalion the East Surrey Regiment: James Dunbar-Brunton to be Surgeon-Lieutenant. 4th Volunteer Battalion the East Surrey Regiment: The undermentioned gentlemen to be Surgeon-Lieutenants: Thomas Mahon Morton and Williams Henry Frome Young. 2nd Volunteer Battalion the Hampshire Regiment: Surgeon-Major R. T. Cæsar to be Surgeon-Lieutenant-Colonel. 5th (Perthshire Highland) Volunteer Battalion the Black Watch (Royal Highlanders): John Anderson to be Surgeon-Lieutenant. 4th (Stirlingshire) Volunteer Battalion Princess Louise's (Argyll and Sutherland Highlanders): Surgeon-Captain A. D. Fraser to be Surgeon-Major.

Memorandum.—Rifle: The undermentioned officers are borne as supernumerary whilst serving with the Royal Army Medical Corps in South Africa:—4th (Cambridge University) Volunteer Battalion the Suffolk Regiment: Surgeon-Lieutenant R. W. Michell. 1st Volunteer Battalion the Duke of Wellington's (West Riding Regiment): Surgeon-Captain G. G. Oakley. 6th (Fifeshire) Volunteer Battalion the Black Watch (Royal Highlanders): Surgeon-Captain C. E. Douglas. 9th Lanarkshire: Surgeon-Lieutenant J. C. Taylor.

"TACTICS FOR SANITARY TROOPS ON THE FIELD OF BATTLE."

Under the above heading Captain Lœffler, who is a staff officer in the German army, has written a short but comprehensive manual[1] for the information and guidance of all concerned in active military operations, whether they belong to the combatant or to the departmental branches of the service. Adopting as his foundation a small force consisting of two army corps, a reserve division, and a division of independent cavalry the author formulates a series of typical military situations, inclusive of outpost affairs, skirmishes, ambulant engagements, and pitched battles, indicating with great precision the duties of medical officers, both administrative and executive, and showing how the slightly wounded should be disposed of as well as by what means the more seriously injured are to be transferred to the rear preparatory to their removal to stationary hospitals. Captain Lœffler's little work, which does not trench at all upon purely medical matters, is well conceived and concisely executed. For the first time in official or semi-official military literature the officers and men of the medical department are treated as soldiers. It is true that from the point of view of a commander, whose *summum bonum* must necessarily be the destruction of his opponents, the relative importance of life-savers can be only small; but in this humane age public opinion insists upon prompt medical aid being forthcoming on the field of battle, and the more the work of the men who have to afford it is facilitated by their assimilation to the men in the fighting rank the better it will be for the solidarity of the entire army. The men, equally with the officers of the Royal Army Medical Corps, are debarred from the satisfaction of striking a blow aggressively, while for lack of sufficient training their efforts in self-defence cannot be supposed to be other than crude and impotent; and yet they are expected to share in all the battle risks of the combatants, besides braving others of a different nature, but just as dangerous to life, if not more so, after the excitement is all over and done with. Throughout Captain Lœffler's book the military status of medical officers is fully recognised. In its pages the reader can see the principal medical officer by the side of his General prior to an engagement, receiving the chief's instructions in company with the other subordinate commanders, and explaining for their benefit how he proposes to make his section fit into the general plan. As the recognised head of an essential portion of the force he is accorded, in so far as his own department is concerned, the attributes of an adjutant-general, being empowered to issue his commands, "By order of the general officer commanding the troops." The issue of this manual marks a distinct step in advance, indicating, as it does, the unequivocal position to which German military medical officers have attained. A volume similar in scope and to a certain extent in treatment has been prepared at the headquarters of the French army and will shortly be published. We sincerely trust that it will not be long before the example thus worthily set is followed by our own military authorities.

TRANSVAAL WAR NOTES.

The Imperial Yeomanry Base Hospital, which has been erected at Deelfontein, about 30 miles to the south-west of De Aar, was opened on March 17th.

A bed for the Imperial Yeomanry Hospital has been endowed by Jewish boys and girls of Cape Town, and the endowment of another bed is promised by the Israel Lodge.

The *Winifredian* arrived at Southampton on Monday, March 19th. She brought 170 men from South Africa for the Royal Victoria Hospital, Netley.

The Hospital Ship *Princess of Wales* has left on her second journey to South Africa.

The Welsh Hospital is expected to leave England in about ten days, Professor Thomas Jones, M.B Lond , F R C.S.Eng , Mr. J. Lynn Thomas, F R.C S.Eng , and Mr. R Mills-Roberts, F.R C S.Edin , will act as surgeons, and Mr. Laming Evans, M B. Cantab., F.R C S , late house surgeon, St. Bartholomew's Hospital, and Mr Herbert Davies, M.B , Ch B. Vict., senior house surgeon, Stoke-on-Trent Infirmary, as assistant surgeons. Five dressers and nine or ten nurses will complete the staff. The hospital funds now amount to over £6000 and among the subscribers during the past week have been H.M. the Queen £100, H.R H. the Prince of Wales £50, and H.R H the Duke of York £20.

The late Sir William Lockhart.

In the death of the Commander-in-Chief of Her Majesty's forces in India the country and the army have sustained a great loss, and we cannot refrain from paying a sincere tribute of respect on the part of the British and Indian medical services to his memory. The late Sir William Lockhart had a very distinguished career and was a very brave man of quite exceptional qualities. He came of a good stock; his uncle was John Gibson Lockhart, the son-in-law and biographer of Sir Walter Scott, and Sir William Lockhart was himself, apart from his high military reputation, a man of ability and culture and possessed an excellent knowledge of German. He was very wise in counsel, decided and prompt in action, and eminently honest and considerate in his dealings with all—and not least so in the case of officers of the medical services. Notwithstanding that he was known to have been for a long time in delicate health his death was a surprise and a real grief to all who had the privilege of his acquaintance. He looked as he was, every inch a soldier—a handsome man of fine physique, to whom independence, courage, and self-sacrifice were natural and instinctive

A Royal Naval Medical Reserve.

Our contemporary the *Army and Navy Gazette* contains a communication signed Louis Vintras, M.D., B.Sc , medical officer R.M.S. *Orinoco*, regarding the value of having competent reserves in all branches of the services. Dr. Vintras suggests, *apropos* of the call that has been made on the civil profession to supplement the Army Medical Service during the campaign in South Africa, that a Royal Naval Medical Reserve might be organised with very little expense to the State out of the number of medical men who have passed several years of their career in the service of one or another of the mail lines, who are used to the sea, have a knowledge of the medical aspects and hygiene of medical life, who are experienced in tropical diseases, and thoroughly inured to rapid changes of climate. The idea seems a good one and fits in with that of the Naval Medical Reserve composed of officers of the large mail companies. Dr. Vintras asks for communications from persons in sympathy with such a movement, or who have suggestions to offer concerning it, to be addressed to him at 19A, Hanover-square, W.

Mentioned in Despatches.

In a despatch from Lord Methuen on the action at Magersfontein on Dec. 10th and 11th, sent by Lord Roberts to the Secretary of State for War, occur the following passages:—

"Major O'Donnell, Royal Army Medical Corps, and Lieutenant Delap, Royal Army Medical Corps, were indefatigable in attending wounded under fire." Black Watch.—Lieutenant Douglas, Royal Army Medical Corps, showed great gallantry and devotion, under a very severe fire, in advancing in the open and attending to Captain Gordon (Gordon Highlanders), who was wounded; also attending to Major Robinson and other wounded men under a fearful fire."

Sir George White.

It will be remembered that the gallant defender of Ladysmith in a brief public speech of thanks for the congratulations tendered to him after the relief of that garrison incidentally adverted to the fact that he was at the time suffering from fever with a temperature of 102°F. Everybody will have learned with regret that Sir George White did not recover his health so rapidly as could be desired and that he has wisely embarked and is returning to this country where all, without exception, wish for his speedy recovery. Sir George White, it is needless to add, went through a most trying time during the long siege, and, in addition to the hardships and privations he underwent, he had all the care and great responsibility of the position. The part he played was worthy of him, and the siege will hereafter occupy a prominent place in military history.

Fruit for the Military Hospitals.

Lady Haliburton in a letter to the *Times* says: "...... I have undertaken to send weekly to Netley Hospital a small supply of fresh fruit for the use of the invalids *returning* from South Africa. Many others, if aware that they might enjoy this privilege, would no doubt gladly avail themselves of such an opportunity of usefulness by sending regular supplies of fruit to the various large military hospitals scattered throughout the United Kingdom. ......" It is to be hoped that many others will follow Lady Haliburton's example.

The total number of conscripts for the French army last year, says the *Army and Navy Gazette*, shows a reduction of nearly 15,000 on that of the previous year. This noticeable drop has caused some uneasiness. The fundamental cause of the diminution is doubtless due to the stationary state of the population, but it is also a fact that there has been a special cause at work. The medical examination of the conscripts has been far more severe than for several years past.

Major W. Dick, M.B., F.R C S. Edin., R.A.M.C. (who is acting for Colonel W. F. Stevenson, M.B. Dub , R A.M C., as Professor of Military Surgery in the Army Medical School, Netley), having been relieved of the charge of the Surgical Division of the Royal Victoria Hospital, Major Birt, R A.M.C., has been appointed to the office.

The following gentlemen have been ordered to join the Army Medical School as surgeons on probation for the Royal Army Medical Corps:—Mr. H. E. Weston, L S A., St. George's Hospital; Mr. J. G. Churton, M.R C.S. Eng., L.R.C.P. Lond.; Mr. A. E Hamerton, M.R C.S Eng., L R C P. Lond., Leeds School of Medicine.

Royal Army Medical Corps messes have now been established in India to which the Government grant 80 and 100 rupees per mensem respectively where eight or ten officers form the mess.

The following civil surgeons having arrived at Netley are posted as stated: Mr. Marriott to the huts for duty, and Dr. A. C. Profeit to the surgical division.

"CROOK v. CROOK AND HORROCKS."

To the Editors of THE LANCET.

SIRS,—Will you permit me through your columns to thank all those who have written to me letters of sympathy and congratulation and also to thank Dr. William Duncan and many others who have expressed a desire to help to defray my costs. I quite appreciate the kind motive and am very grateful, but I prefer that no subscription list should be started on my behalf.

I am, Sirs, yours faithfully,
PETER HORROCKS.

"THE NITRO-PROPIOL TEST FOR SUGAR IN URINE."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Feb. 17th there was a notice of Teusch's Nitro-Propiol Test for sugar which induced me to send for a bottle of the tablets in order to compare it with the ordinary method by Fehling's solution. According to the directions supplied with the tablets we are told to dissolve one tablet in about three drachms of water, add 10 drops of the suspected urine, and boil slowly for from three to five minutes. A fine colouration of indigo blue is said to take place if sugar be present, the indigo being deposited when the fluid is allowed to stand. It is at once obvious that boiling for from three to five minutes is a disadvantage for two reasons · it takes up a good deal of time and it is impossible to boil continuously for so long in a test tube without explosions of steam, so that the process must be carried out in a flask or capsule. But this is not a serious objection if the method were so accurate as not to need confirmation.

It is well known that the power of reducing cupric oxide is not peculiar to grape sugar but is shared by a good many other substances which are frequently present in sufficient quantities in the urine to cause at any rate a partial reduction of the test solution, so that a method which would be equally delicate and positive in its results and which would stand in no need of confirmation by other means would be a boon to clinical medicine. From this point of view I cannot speak very highly in favour of the new test. A case of diabetes under my care which has improved so much that the sugar in the urine for a long time has been less than 1 per cent., and estimated by Fehling's solution gives 0 8 per cent., failed to give any reaction at all with Teusch's test. On the other hand, the urine I have been examining this morning, which deposits an abundant sediment of cayenne-pepper-like crystals of uric acid, reduced Fehling's solution partially so as to give a dirty yellow precipitate. After filtering through animal charcoal, according to the method advocated by Sir William Roberts for removing reducing substances other than sugar from the urine, the test solution remained perfectly clear, bright, and unaltered in colour. I should say, therefore, that this urine does not contain sugar, but that the reduction is due to uric acid; however, after boiling in a capsule with Teusch's test a blue film of indigo was deposited upon the capsule.

In order to clear up this point I had this urine examined by fermentation and with phenyl hydrazin, both of which gave a negative result. In this case, then, Teusch's test is out of harmony with the results of three methods which are generally regarded as trustworthy. Therefore it does not seem to possess any advantage, either in rapidity of application, delicacy, or accuracy, over Fehling's solution.

I am, Sirs, yours faithfully,

March 19th, 1900. ROBERT SAUNDBY.

THE MIDWIVES BILL.

To the Editors of THE LANCET.

SIRS,—Perhaps it may help if I call attention to the fact that the present Midwives Bill is based upon two principles—one that of control and one that of improving the status of the midwife. For practical purposes these two principles are incompatible, for with improvement in status control of any value is impossible. It is therefore idle to talk of amendments until it is decided upon which principle legislation is to be based. I cannot help congratulating the gentlemen of the Obstetrical Society of London upon their success. They have succeeded in making it to appear before the world that their society is in favour of legislation, and, besides their society, both corporations. They have also hauled into the meshes of their net the council of the British Medical Association. As you point out in your issue of March 17th they are really backed by a very small number of the profession, as I ascertained some years ago. These congratulations I cannot accord to the profession as a whole, which has allowed, by its failure to provide an organisation capable of defence, a few persons to give away the mass. Perhaps the sense of danger, which many will not appreciate until it is too late, will hasten the organisation of the profession. At the present moment a study of the history of the Bill will show conclusively that the profession is powerless in the face of an organised body, however small and unimportant. The policy of the corporations is to keep down the general mass of the profession, and a very wise policy, too, from their point of view. It will require a powerful organisation to cope with them. I am, Sirs, yours faithfully,

Hatfield, March 19th, 1900 LOVELL DRAGE.

THE MERITS OF BLACK INSTRUMENTS IN THE EXAMINATION OF INTERIORS.

To the Editors of THE LANCET.

SIRS,—Custom is commonly in error in the construction of specula employed for the illumination of various cavities in that it is generally assumed that they must be made of bright reflecting surfaces. The word speculum itself suggests this so far as it signifies a mirror. Practically many must have observed that the bright specula designed with the object of carrying light further into the cavity illuminated, so far from effecting this object, actually prove disconcerting to the vision by surrounding the dark region investigated with a field of dazzling light. Even supposing that more light is actually carried inwards, which is often doubtful, it must be largely counter-balanced by the reflection backward on to the operator's eye. And when it is remembered that the first physical essential for examining a field darker than its environment is that the pupil should dilate it is obviously unscientific to counteract this by the inevitable contraction which the reflected light from the speculum induces. This has been realised to a certain extent by the construction of black vulcanite aural and other specula, which are of course useful by assisting dilatation of the pupil. And any surgeon using the black nasal specula I have had constructed for me by Messrs. Mayer and Meltzer will realise the immense gain when contrasted with the ordinary silvered instruments. Extending this principle in the use of intra-laryngeal instruments I have had forceps similarly blackened. The result is of considerable gain when removing minute papillomata from the vocal cords, in which case any condition which prevents contraction of the pupil while examining the relatively dark interior of the larynx must be of essential value And I believe the gain to the operator is as great here as in examining the nose with blackened specula. Presumably there is no reason why nasal forceps, &c., should not be similarly blackened, though the need is obviously not so great as in operations upon the larynx. Messrs. Mayer and Meltzer have spent much time in discovering a satisfactory method of blackening, and, in spite of disappointments, have, I think, succeeded admirably.

I am, Sirs, yours faithfully,

March 19th, 1900. GREVILLE MACDONALD, M.D. Lond.

"THE CORONERS' SOCIETY OF ENGLAND AND WALES."

To the Editors of THE LANCET.

SIRS,—Mr. Braxton Hicks's letter of March 12th, published in THE LANCET of March 17th, informs the general body of the medical profession of an opinion expressed by the above-named society on the questionable duty of the medical practitioner in attendance being bound to report to the coroner for his district all deaths other than those arising from natural causes. While convinced that Mr. Braxton Hicks correctly states the opinion of this society, to which he acts as honorary secretary, may I be permitted to point out that the profession at large are not obliged to abide by any opinion or resolution expressed by this or any other kindred society, but by the ruling of the courts of justice on this point? Till such definite ruling is obtained they can afford to ignore all such resolutions.

Whilst candidly admitting "*that no particular class of persons is mentioned whose duty it should be to inform the coroner*" (the italics are mine), he proceeds to postulate that the hypothetical conjectures put forward in "Jervis on Coroners" should be regarded as the law on the subject, completely ignoring the fact that the pious private opinions of that worthy gentleman, unqualified by any definite ruling on the point at issue, do not rise to the level of authority. Even admitting "Jervis on Coroners" to be correct in stating the law on this point—i e., this duty devolves upon those who are in attendance on or about the deceased *at the time of death*—I fail to see how such a ruling can affect the medical practitioner in the *majority of cases* which call for an inquest or an inquiry by the coroner—cases in which no medical practitioner is in immediate attendance on the deceased *at the time of death* or in which the only attendance on or about the deceased commenced *after his death*.

The savoury threats held out by the council of this *private* society of "an indictment at common law for not *fully* stating the cause of death" may be ignored by all *who act in good faith*. For should any such action be entered, the *onus* of proving "*evil intent*" and "*wilful* suppression of the truth" must fall on the plaintiff. *Apropos* "the law relating to coroners," may I ask Mr. Braxton Hicks for a statement of the fees paid to the medical profession for reports (expert opinion) regarding the cause of death in cases closed by an inquiry without inquest, the reports being forwarded the coroner at the request of his officer? The coroner for the ancient city of Rochester pays, and prior to 1897 the coroner for the Sittingbourne district, Kent, has paid, a fee of 10*s.* 6*d.* for each report. Sequent to 1897, this fee has been disallowed by the Kentish County Council, and medical men thereby burked of their legitimate dues. My professional brethren should note that in dealing with a coroner who refuses to pay for such reports not to furnish him or his officer with any expression of a professional opinion as to the cause of death without a subpœna.—I am, Sirs, yours faithfully,

CLARENCE A. WRIGHT, F.F.P.S. Glasg., F.R.C.S. Edin.

Leytonstone.

"DEATHS UNDER CHLOROFORM."

To the Editors of THE LANCET.

SIRS,—With reference to the letter of Lieutenant Clayton Lane, I.M.S., at page 731 of THE LANCET of March 10th will you permit me to draw attention to a few points which he has apparently overlooked? I quite admit that my opinion, or "guess" as he prefers to call it, is based on purely circumstantial evidence; that is perhaps unavoidable in such cases. Lieutenant Lane assumes that the respiration began to fail first, but why he should do so is somewhat difficult to conceive since the report states that "the breathing continued being slow and stertorous" some time after the appearance of dangerous symptoms

Again, as the medulla is one of the last parts of the brain to become affected by chloroform, respiratory paralysis only comes on in the late stages of anæsthesia; in the case in question the dangerous symptoms appeared in the second or excitement stage, while even the superficial reflexes were still active. While agreeing and sympathising with Lieutenant Lane in his regrets at the incompleteness frequently observed in the reports of deaths under chloroform, a little reflection confirms one in the belief that many of the defects are unavoidable so long as the patient's life is considered of more importance than the solution of a purely scientific problem.—I am, Sirs, yours faithfully,

GEORGE MOWAT, M.B., Ch.B. Aberd.

Royal Infirmary, Wigan, March 19th, 1900.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

Famine and Plague in India: Four Millions of People Under Relief.—The Recrudescence of Plague in Calcutta.—The General Mortality in Bombay, 170 per 1000 per annum.—The Enormous Plague Expenditure.—The Terrible Mortality in Bombay.—Increase of Plague in Calcutta.

FAMINE and plague are the two chief factors of medical interest at the present time. The famine is of almost unparalleled magnitude and is very widespread. The numbers in receipt of relief have now approached four millions and increases are weekly reported from several provinces. No such number of persons has ever before been simultaneously relieved by any Government in the world. Unfortunately there is every likelihood of these totals being still further increased during the spring and summer months. In Western Rajputana 90 per cent. of the cattle have been lost. Except in some native states mortality from famine has been almost completely suppressed. There are not now, as on former occasions, the "poor emaciated wastrels, the living skeletons, whose pitiful likenesses nearly broke our hearts when they appeared in the illustrated papers three years ago." Public charity has been called for and the call has been grandly answered. Some of the native princes have given liberally. The distributers of the famine fund make no discrimination between the claims of native States and British India. It is perhaps only in this famine that organised relief in native territory has been carried out, as in 1897 such relief was experimental. The famine is now most severe in the native States.

Points of interest about the plague epidemic continually arise. The disease has now taken hold of Bengal and is spreading fast. As I predicted there is a recrudescence in Calcutta The plague mortality has been rising steadily since the end of January and the returns for last week show 199 deaths. The outbreak in Calcutta has not yet alarmed the native mind and large numbers still refuse to believe that the disease is plague at all, but comfort themselves with the title of bubonic fever, milder forms of which they think they have known in Bengal for many years The regulations being so mild there is no ground for any complaints against the authorities. Should plague really develop seriously, as in Bombay and Poona, the organisation must show itself as helpless as it is insufficient. The rate of general mortality now exceeds 50 per 1000 per annum, the normal being about 37. There is every indication of a very serious development. The outbreak in the Patna district has much increased but it does not seem to have attracted much public attention. Nearly 1000 deaths occurred last week. The people refuse to follow the traditional plan of evacuation which has proved so successful in Dacca, Faridpur, Backergunge, and in Darbhanga. Someone appears to have poisoned their minds just in the same way as someone poisoned the minds of the people of Calcutta with regard to inoculation. The consequence is that the disease has spread rapidly and is now threatening South Behar.

Of Bombay city the record is terrible, no less than 2701 deaths having occurred during the past week. The number of those dying from plague is greater than has ever been known. The death-rate is over 170 per 1000 per annum. *The official returns only give the small number of 641* deaths from plague. Small-pox is still raging but probably does not account for more than 30[illegible] in the week.

The plague expenditure in Bo[illegible] been very large. A recent return shows that up[illegible] 31st, 1899, the total expenditure was Rs. 4,08[illegible]ual roughly to about £270,000). During the [illegible] that is, since the dissolution of the Plague [illegible] the expenses have been much reduced, but, [illegible] this period something like £35,000 have been [illegible] administration. The returns for the whole [illegible]7 deaths from plague. It would probably n[illegible] wrong to double this estimate. In the Jullunder district of the Punjab more villages are being attacked. The recrudescence at Karachi has aborted and the plague mortality has now sunk to very small dimensions. These abortive attacks have occurred at other places, but there seems no explanation to account for them. Though not serious in themselves they keep the disease slumbering ready to awaken to renewed activity at a future period. I am afraid that they form no indication of a decadence of the epidemic

The latest weekly plague statement for India ending Feb 24th shows a marked increase in the number of deaths and the week closes with 3184 fatal cases, against 2597 in the previous week. The increase is due to the further development in Bombay and in the Bengal Presidency. In Bombay city the general mortality again surpassed the previous maximum and 2831 deaths were recorded. Of this number 263 were attributed to small-pox, but the official figures only return 768 deaths as due to plague. If the truth were known probably 2000 deaths occurred from plague alone. This terrible general mortality very nearly touches a rate of 180 per 1000 per annum. In Calcutta the outbreak is developing very rapidly and now after only five weeks' increase the plague mortality is double what it amounted to during the worst week of last year!

I regret to say that the rapid increase and the discovery of more living cases foreshadow a still further development of the outbreak. The general mortality at the present time exceeds the average by just about the number of the plague deaths and there is no other epidemic to account for the excess. In the Patna district the disease has spread considerably and 1444 deaths were returned for last week. I regret to have to record a renewed activity at Karachi, fresh outbreaks in the Punjab, and that six fatal cases have been reported from Aden.

Feb 26th

UNIVERSITY OF DURHAM FACULTY OF MEDICINE.—Dr. Percival Davidson is now in South Africa with the 5th Battalion Imperial Yeomanry (including Northumberland and Durham and Shropshire Companies), to which he is surgeon. Dr. Davidson is a graduate of Durham University and was for some time senior house physician at Newcastle Royal Infirmary. Dr. W. L. W. Walker, a graduate of Durham University, who was mentioned in THE LANCET of March 10th (p. 739) as being attached to one of the South African Companies of the Northumberland Yeomanry, is attached to a hospital on the lines of communication.

THE ORGANISATION OF THE PROFESSION.

NORWICH.—ABORTIVE ATTEMPTS TO DEAL WITH CLUB PRACTICE.—GOOD RULES THAT ARE NOT APPLIED.—THE RÔLE OF THE MEDICO-CHIRURGICAL SOCIETY.

(FROM OUR SPECIAL COMMISSIONER.)

THE position of affairs at Norwich is certainly not encouraging. This town may serve as a typical example of difficulties that have not been overcome and yet where some efforts have been made to deal with the existing grievances. So far back as the month of April, 1897, a meeting of all the members of the medical profession was held in the library of the Norwich Medico-Chirurgical Society. Most of the practitioners of the county belong to this association and it meets once a month for the purpose of reading scientific papers. When, however, ethical questions became prominent they were also discussed. Some of the members urged that energetic measures should be taken, others were opposed to any such action, and during the year 1896 so many heated discussions occurred that some fears were expressed that the association would be broken up. However, the reform party was so far successful that at the annual meeting for the year 1896 a new rule was accepted and worded as follows:—

> Any registered medical practitioner who shall be adjudged guilty of, and persist in, unprofessional conduct as defined by the code of rules adopted by this society shall be ineligible to be a member of this society.

It was, however, easier to adopt rules than to enforce their application. Some of the local practitioners were receiving incomes from the medical aid organisations In one case such income was said to amount to about £300 annually and it was stated that paid canvassers were employed. In reply it was urged that the canvassers were only collectors and did not tout. Indeed, as the discussion continued, it seemed as if the application of the new rule would involve the expulsion of the greater part of the members of the Medico-Chirurgical Society. Many practitioners had also private penny clubs of their own. Others had commenced practice in Norwich as the salaried officers of the Friendly Societies' Institute and then had taken some of the patients away from this institute and thus built up for themselves a private practice. They were therefore not very anxious to abuse the bridge on which they had crossed. Others complained that the Friendly Societies' Institute had been the means of introducing a low class of medical men into the town and this accusation did not tend to sweeten the acerbities that arose. Thus, it was found that while most of the practitioners, were ready enough to throw stones each had his own particular skeleton which he was anxious to conceal If the rules were strictly applied terrible ruptures would ensue, old well-established social ties would be broken; and there seemed to be no leader, no organised force, to give a direction and to indicate a policy that could unite the profession and bring about an attack on the line of least resistance.

In one respect Norwich was in a much less favourable position than the neighbouring town of Yarmouth. At the latter town the medical practitioners had with great unanimity constituted a medical union before the friendly societies established their medical institute. At Norwich, on the contrary, a similar institute had been in existence for about a quarter of a century. Some 25 years ago the medical practitioners only received 3*s* per annum from the members of the benefit societies and for this small sum they had to give medical attendance and medicine. A movement leading up to a sort of strike was then started among the members of the profession, but there was a lack of unity. Still, the agitation, though not sufficiently unanimous to obtain the desired reforms, nevertheless seriously alarmed the friendly societies and led them to form an amalgamation by which the Friendly Societies' Medical Institute was created, and here they employed two medical men at fixed salaries Most of the clubs or benefit societies went over to this institute, but some of them agreed to pay more and retain the services of their medical officers. Now that this institute has existed so long and has acquired well-established vested interests it cannot be combated with the same facility as could the newly established institute at Yarmouth. The Norwich Friendly Societies' Medical Institute has probably some 10,000 members. It employs two medical officers and one of them lives on the premises Sir Peter Eade and Mr. Cadge were the consultants, but when all the grievances were exposed and the evils of the system were made manifest both the consultants sent in their resignations, so that the efforts made have not been altogether futile.

There is also the Norwich Free and Provident Dispensary which is a semi-charitable institution, being supported partly by the subscriptions of the members and partly by donations. It employs seven medical officers who are paid according to the number of members on their list, the highest payment being £300 and the lowest £80 per annum. The question naturally arose as to whether this dispensary could be considered as an organisation worthy of support by the medical profession. This was soon brought to a test. Seeing how deeply the practitioners of Norwich are involved in the system of contract work it seemed impossible suddenly to put an end to the clubs or medical aid organisations. Therefore, at the general meeting held by the profession in April, 1897, an attempt was made to meet these difficulties, not by abolishing contract work but by substituting for the existing institution a provident medical service organised and managed exclusively by the medical profession. In a word, Norwich sought to imitate the example set by Eastbourne and Coventry. Previously to this a committee had met on six different occasions to draft a scheme. According to this proposal a dispensary was to be established with the title of the Norwich Public Medical Service. There was to be a central office where patients could attend to obtain advice and medicine. At Coventry and at Eastbourne it may be noted that there is no such office and some doubts may well be entertained as to the wisdom of having such a central office or dispensary. It adds considerably to the working expenses and compels the medical officers to absent themselves from their own surgeries so as to attend at the dispensary. The patients on their side have to go greater distances, and have to crowd together in a waiting-room where they may lose a considerable amount of time. As a rule the patients prefer going to the private surgery of a medical practitioner living in their immediate neighbourhood. However, this is only a practical question and not a matter of principle. The Public Medical Service, of course, was to be self-supporting and was to be governed by an elected committee. All qualified medical practitioners, not practising as homœopaths and having resided 12 months in Norwich, might become members of the medical staff if they signed an undertaking not to accept in future any club offering less remuneration. Further, they were to have no professional intercourse whatsoever with any practitioner who was connected with medical aid societies or similar institutions if the latter canvassed for members in the interests of individual practitioners, had not imposed a wage limit, and virtually sweated their medical officers by making a profit out of their work and paying them inadequately. The Public Medical Service was to accept as members artisans and their families and others who might be considered suitable by the committee if they made correct statements as to their income or weekly wage and if this did not exceed the sum of 35*s*. per week. The candidates were to be medically examined and, if accepted, charged 6*d* entrance fee and 2*d*. for their cards. After that adult males and females would have to subscribe 4*d*. per month and children under 14 years of age 2*d*. per month. A family, however numerous, would not be charged more than 1*s*. per month Several practitioners protested that the payment for adult females should be 6*s* per annum as they required more attendance than males Members more than 60 years old or actually in ill-health when joining were to be charged an entrance fee of 5*s* Domestic servants were not to claim attendance at their employers' houses If a member's income increased and exceeded the wage limit he was to be struck off the books. The fee for confinements would be 20*s*. payable in advance, miscarriages 10*s*., and vaccinations 2*s* 6*d* There was to be also a special scale for surgical operations Of course, the members were free to select their medical attendant The committee that prepared this scheme consisted of 14 practitioners and it was adopted at the general meeting of the profession held in April, 1897.

Unfortunately the iron was not struck while it was hot. Shortly after this meeting a deputation went up to London to discuss the entire question with the General Medical Council, the Royal College of Surgeons of England, and the Royal College of Physicians of London. Much time elapsed before this deputation presented its report and then it seemed that nothing very satisfactory had been done. Indeed, the visit to London acted as a sort of wet blanket and the enthusiasm which had at first been evoked cooled down. All the practitioners of Norwich were still anxious that the Public Medical Service should be established, but each individual preferred that others should begin and reserved for himself the privilege of joining later, when the enterprise would have proved successful. The Council of the Norwich Medico-Chirurgical Society sent out notices reminding members of the rules and then it was proposed to report all practitioners who failed to observe them. But this was only a threat, no one seemed to have the courage to act. There was some talk, but it was only talk. At last it was suggested that an effort should be made to work with the Norwich Free and Provident Dispensary, and that the scheme of the Medical Service should be welded with that of this old and well-established institution. The Dispensary, however, did not feel inclined to open its doors to all the practitioners of the town. The members were willing to add two medical officers to their staff, but that was all. Of course this would only increase the existing evil. The complaint against all dispensaries of this description is that they create a monopoly, as is illustrated by the provident dispensaries of Leicester, Coventry, Northampton, and the like. Under the mantle of charity and with the aid of a lay committee a small body of medical practitioners get an enormous list of patients and more than their share of such contract work as may be necessary to secure medical attendance for the poorer classes. The true course, of course, was to throw this work open to all practitioners, and it was no solution of the difficulty to increase the number of privileged practitioners on the staff of the Dispensary. The remedy consisted in the abolition of all privilege. Some of the medical officers were on the managing committee of the Norwich Free and Provident Dispensary, and they, at least, should have understood this, but they altogether failed to prevent the adoption of the proposal to add two more medical practitioners to the Dispensary staff. Thus so far the attempt to establish a Public Medical Service has done more harm than good.

Yet in spite of all this weakness and all these failures there is a strong feeling in favour of reform and a desire to act; but there is neither leadership nor unanimity. Thus individual practitioners are fighting by themselves; there is a sort of guerilla warfare and no disciplined concerted action. For instance, the two medical officers who are in the employ of the Friendly Societies' Medical Institute are consistently boycotted; no one will meet them, and if one of their patients requires a second opinion or consultation the patient calls alone on one of the consultants and pays his guinea fee. Such payments being frequently made prove that many members of the Friendly Societies' Medical Institute have incomes that exceed any reasonable wage-limit. There are likewise many members of the Independent Order of Oddfellows, Manchester Unity, who are in good positions. These are tradesmen, yet they only pay 4s. a year for medical attendance. If it is necessary to perform an operation on one of the members of the Friendly Societies' Medical Institute the operating surgeon writes to the medical officers of the Institute and warns them to keep away. Thus a case was related to me of a member who had suffered from typhoid fever and was attended through this illness by the medical officer of the Friendly Societies' Medical Institute though he only paid 3s. per annum. When, however, it was necessary to perform an operation on the wife of this member he engaged a leading surgeon of the town and paid him £20. If he could pay £20 for his wife it seems obvious that he could have paid more than 3s. for medical attendance on himself during so serious an illness as typhoid fever. Thus there can be no doubt as to the abuse that prevails. Still the members of the profession do not know how to act.

If little or nothing has been done in respect to club practice some improvement has been effected in regard to hospital abuse. The members of the medical staff of the Yarmouth Hospital raised this question and awakened the admission committee from its dormant condition. A board was put up explaining that the hospital was a charitable institution intended only for the relief of the poor. The practice of receiving paying patients at the hospital was abolished and during the course of the year a few patients have been refused admission on the ground that they could afford to pay the usual fees. Also club patients were in the habit of coming to the hospital. This has also been abolished and now none are admitted unless at the special and written request of their club medical officer. As a result of these measures it is thought that the abuse of the out-patient department is not so prevalent as it was formerly. There is no agent to inquire at the patients' homes, but the porter is a shrewd man and he keeps a sharp look-out. One of the clerks also is well acquainted with the members of the benefit societies and he helps to prevent abuse.

The question arises as to what should be done. At present the body which is best able to deal with the points at issue is the Norwich Medico-Chirurgical Society. It possesses close upon 150 members, of whom about a quarter reside in Norwich. According to Rule 1 its object is not only the cultivation and promotion of medicine, surgery, and the branches of science connected therewith, but also the "consideration of public matters affecting the profession," and the support of a medical library. Therefore the dealing with ethical and economical questions is quite within the scope of the accepted programme. Further, Rule 6 states, as already mentioned, that any registered medical practitioner who shall be adjudged guilty of unprofessional conduct shall be ineligible as a member, and it adds:—

> The rules adopted by this society are those formulated by Dr. Styrap, with clause appended with regard to medical aid associations defined as associations formed as trade speculations, carried on by lay proprietors for the purpose of deriving pecuniary profits from the earnings of members of the profession, and pushed by means of advertisements or by the employment of paid canvassers who tout and solicit the patients of other practitioners; and that it be deemed unbecoming and unprofessional for any member of the profession to lend his name or to associate himself in any way with such societies or clubs.

We have seen, however, that so far this rule has not been properly applied, and there is a natural tendency to inquire whether any other form of organisation would be able to deal more efficaciously with these problems. There also exists the East Anglian Branch of the British Medical Association, but it does not often discuss ethical questions. Nor does it meet regularly in any one particular place, but has gatherings in different towns, so that it may not meet in Norwich more than once in the course of three years. What is required is a medical union formed to deal exclusively with ethical and economical questions and this in a militant and constant manner. Such a union would consist of those who were in active practice in the town, but the fact that it had been created by the Medico-Chirurgical Society would bring up the support of a large number of practitioners established in neighbouring towns and districts. This would be most useful, notably in preventing the importation of medical practitioners to take up the work which members of the medical union might in view of obtaining necessary reforms refuse to undertake. The Medico-Chirurgical Society may convoke a meeting of the entire profession and then open its doors to all comers, but that does not suffice. A permanent link must be established. The practitioners must be brigaded and they must be brought under some form of discipline which shall harmonise with the opinions of the majority. The members must exercise some ingenuity to render such a union and its gatherings attractive to those who might otherwise be inclined to hold aloof. There are courtesies and civilities that are sometimes more effective than the most telling arguments. Nobody really likes to b ostracised, and before war is definitively declared all arts o persuasion should be employed. This is the work of a unio rather than of a somewhat exclusive social and profession club; and it is for these reasons that the Norwich Medic Chirurgical Society might be well advised in seeking establish a medical union of a militant character.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Bakers and Confectioners' Exhibition.

THIS is an age of exhibitions and Manchester is s without one. That now being "run" is in connexio the pastry-cooks, confectioners, bakers, and allied tra the United Kingdom, and it is held under the auspices National Association of Master Bakers in conjunctio the Manchester and Salford Association, of which most of us are, it is to be feared, grossly ignorant held in St. James's Hall, was opened on March 12 is the fourth of its kind. It seems that the prize given amount to £250. It is no doubt a good th there should be as few secrets as possible wit to the preparation of food, but it is by no me that the public will learn much from seeing the finished products of the confectioner's art. The exhibition remains open till March 21st and daily judging of the bread and confectionery takes place. It is questionable if what is called the main feature of the exhibition is specially conducive to speedy and unobtrusive digestion, for it consists of a fine show of bridecakes in all their artistic beauty. This show is said to be unique, or, as the report says, "*somewhat* unique, no such artistic display having been seen not only in the provinces but even in London." Perhaps the bridecake has caused some obscurity in the language. There is more in the art of confectionery than a mere ordinary man supposes. The President said that "the exhibits were wonderful examples of excellence and accuracy of touch which was only to be acquired by constant and lengthened practice," and a gentleman from Hull, the President of the National Association of Master Bakers and Confectioners, said that "the bakers produced the best of bread and the confectioners exhibited bridecakes and fancy confectionery which were most artistic in design and in workmanship and quality." We shall, no doubt, hear before long of a Burne-Jones among the bakers or a Dante Rosetti among the confectioners. It gives one a shock to remember amid all this the stories—true not long since—of phthisical bakers toiling amidst the foulness and heat of ill ventilated, underground bakehouses. Are any of these stories true now?

Asylum Accommodation in Cheshire.

Notwithstanding the recent enlargement of the Cheshire Asylum at Upton, Chester, which has given altogether accommodation for 1000 patients, the asylum at Parkside, Macclesfield, needs enlargement. At a joint meeting of representatives of the Cheshire County Council and the county boroughs of Stockport and Birkenhead, held on March 9th at Crewe, plans for the enlargement were approved. The arrangements will allow of the best classification of the various phases of lunacy. The cost per bed is estimated at £250 and the total cost of the enlargement at £70,000 But this is not expected to be sufficient for more than 10 or 12 years. A proposal has been made that cottage homes should be established for imbeciles and chronic, helpless, and infirm patients who want nothing more than care and nurture.

Preservation of Milk.

As the use of most of the preservatives for milk is so much objected to, it is interesting to note a method of treatment described at a recent meeting of the Manchester Literary and Philosophical Society by Dr. F. H. Bowman. He stated that very promising results had been obtained with regard to the preservation of milk by slowly bubbling sterilised air through it. There was no loss of flavour or of nutritive value. Care must be taken to keep the agitation within such bounds as will avoid the effects of churning. Dr. Bowman promised to make a further communication on the method if it proved of practical importance.

Small-pox Hospital for Manchester.

The Manchester Corporation are seeking powers to borrow £60,000 to build a small-pox hospital on Carrington Moss and a lengthened inquiry is being held in the town hall by Dr. S. W. Wheaton, the commissioner representing the Local Government Board. As may be known to many of the readers of THE LANCET the land was bought some years ago in order to get rid of, and to utilise, nightsoil and other refuse by the aid of which several thousand acres of waste land have been reclaimed and rendered productive. The corporation propose to reserve 55 acres for the hospital and its surroundings. It is difficult to find sites remote from dwellings in this populous district and it would be extremely difficult to find another so isolated Of course, the opposition is strong, as it would be anywhere The result of the inquiry cannot be foretold, but if this site is rejected there will be great difficulty in procuring a small-pox hospital for Manchester.

March 20th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Royal Edinburgh Hospital for Sick Children.

SEVERAL appointments have just been made in connexion with the Royal Edinburgh Hospital for Sick Children. Dr. John Thomson has been appointed one of the ordinary physicians in place of Dr. John Playfair whose term of office has expired. Dr. James Stewart Fowler has been appointed to be one of the extra physicians to the institution.

Scottish Association for the Medical Education of Women.

The tenth annual report of the Scottish Association for the Medical Education of Women shows that during the year ending Sept. 30th, 1899, the total receipts amounted to £2395 2*s*. 6*d*. and the total expenditure to £2381 19*s*. 6*d*. At the beginning of the winter session, 1899-1900, 105 students paid the matriculation fee of the College.

The Edinburgh and East of Scotland South African Hospital.

The scheme for a hospital for wounded soldiers in South Africa which was originated a few weeks ago by Lord Provost Mitchell Thomson has been most warmly supported in the East of Scotland. It will be remembered that in the first place the suggestion was that Scotland should provide a hospital ship which would cost about £60,000. Negotiations on the subject were opened with Glasgow, but as that city was unwilling to cooperate the scheme was dropped. The Lord Provost, however, at once took up the lesser undertaking of providing a hospital for the front, and so enthusiastically was the matter taken up by the citizens that in little more than a month practically the whole of the necessary funds were subscribed in Edinburgh and the East of Scotland. It was estimated that for a hospital of 100 beds, to be placed on the lines of communication, a sum of from £12,000 to £20,000 would be necessary. The Lord Provost raised over £6000 of the amount needed before he made a public appeal, and the sum now raised is only a few hundreds under the £20,000 The hospital is to be what is known as a stationary hospital on the lines of communication. The premises will consist of four wards and an administrative block. They will be made of corrugated iron, with wooden floors and a canvas lining. The wards will be each 128 feet in length, 19 feet in width, and eight feet in height to the rafters, across which will be stretched a canvas ceiling. The administrative block will be 185 feet long, 28 feet wide, and nine feet high, while there will be smaller out-buildings for various purposes. Each ward will have 25 beds, with surgery, dispensary, and lavatory accommodation attached. The administrative block will contain separate rooms for the medical staff and nurses, a dining- and recreation-room, and dormitory accommodation for the orderlies. First-class electrical apparatus is being taken out which will furnish electric light to the hospital and will enable the surgeons to make use of the x rays. A soda-water machine, large enough to supply the whole of the hospital with soda-water for ordinary drinking purposes, forms part of the equipment of the hospital, as well as a Chamberland-Pasteur filter, a Berkefeld field service filter, and several smaller filters. The wards will be erected parallel to each other with a space of 60 feet between them. The administrative block will be set at right angles to the other premises and will be stationed 150 feet behind them. These erections, which were supplied by Messrs Humphreys of Knightsbridge, were set up in London, have been passed by the War Office, and have been inspected by the members of the Executive Committee. As the huts are in numbered sections the putting of them up or taking them down will not be difficult. A large stock of medical comforts, including champagne, brandy, whisky, and other liquors, has been presented to the hospital by merchants and others as a token of their interest in the scheme. The drugs and instruments are all of the best and have been supplied by Edinburgh firms. The details of administration have all been already thoroughly worked out, so that the hospital will be ready for use whenever it arrives in South Africa. The hospital staff is to consist of 64 persons. The chief executive officer will be Sir James Clark, Bart, Major, Royal Army Medical Corps. The civilian staff will consist of Professor Chiene as head and Mr. David Wallace as second in command, while Dr. Francis D. Boyd will act as physician to the hospital. There will be four assistant surgeons—Mr. A. H. Watt, Dr C. M. Cooper, Dr G L. Chiene, and Dr James Miller. The members of the staff will be inspected before leaving Edinburgh by the general commanding in Scotland and will leave Southampton on March 24th on board the *Briton*. On March 18th the medical and nursing staff of the hospital attended the military service in St Giles's Cathedral. The sermon was preached by the acting chaplain to the forces, the Rev. Dr. Theodore Marshall. After the service the medical men were addressed by the Lord Provost in the Royal Exchange-square.

Exhibition of Hybrids.

Professor Cossar Ewart is organising an exhibition of zebra and other hybrids to be held from April 2nd to 7th in the Waverley Market, Edinburgh, in aid of the War Relief Funds. He will be glad to receive loans for the week of hybrid beasts, birds, or fishes.

Recital in Aid of the Royal Army Medical Corps Fund.

On the evening of March 14th a musical and dramatic recital was held in the hall of the Edinburgh University Students' Union in aid of the Royal Army Medical Corps South African Fund. The Edinburgh University Musical Society performed several choral pieces, while Miss Clouston, Miss B. Stewart Richardson, and several students supplied the dramatic element. The hall was completely filled. The audience included General Chapman, C.B., and staff, and the Presidents of the Royal Colleges of Physicians and Surgeons of Edinburgh.

Dundee Surgeon for South Africa.

Dr. D. M. Greig of Dundee has received an appointment in connexion with the South African Field Force. Dr. Greig served in the Royal Army Medical Corps for three years after he graduated and began practising in Dundee in 1889, where he holds the rank of Surgeon-Captain in the 1st Forfarshire Volunteer Artillery.

University of Aberdeen.

Rev. John Marshall Lang, D.D., at present minister of the Barony Parish Church, Glasgow, has been appointed Principal of Aberdeen University in succession to the late Sir William Geddes. Dr. Lang is a graduate of Glasgow University and is the author of several religious works. In 1856 he was inducted to the charge of the East Parish, Aberdeen, a post which he filled for two years, but otherwise he has had no special connexion with the "Granite City."—The prospects of the University Buildings Extension Scheme have now considerably improved. Both the town council and the University Court have agreed to adopt the "popular" plan, which provides for the removal of Old Greyfriars Church and the erection of a new church at the junction of Queen-street and Broad-street, and the latter body has acquired at an expense of £10,065 the property required to provide a site for the new buildings, which will cost £10,000 more. For their part the Greyfriars Kirk Session agree to withdraw the legal process raised against the two bodies first named on payment of expenses. The deadlock in the University Buildings Extension Scheme has thus been removed, and if funds can be obtained it will be an easy matter to complete it in such a way as not only to enlarge the Marischal College buildings, but also at the same time to bring about an important street improvement.—There are 67 entrants for the medical preliminary examination which commences on March 23rd.

March 20th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Dublin University Biological Association.

AT the last meeting of the Dublin University Biological Association, which took place in Trinity College on March 15th, a paper was read by the President, Dr. W. R. Dawson, on the Pathological Study of Insanity. After the discussion the following motion was proposed and passed unanimously:—

> That in the opinion of this association it is desirable to establish a central laboratory for the Irish asylums devoted to the study of pathology in relation to nervous and mental diseases.

The Dublin Public Health Investigation Committee.

After a recess of a fortnight's duration the Public Health Committee resumed their sitting on March 20th at the City Hall.

Belfast Port Sanitary Authority.

Mr. Agnew, Local Government Board inspector, held a public inquiry at Belfast on March 14th in reference to an application made by the county borough council of Belfast to the Local Government Board to be constituted the "Port Sanitary Authority" for the whole of Belfast Lough. At present their jurisdiction is confined to that portion of the lough abutting on the city and authority is spread over different bodies who have no means of carrying out the required sanitary regulations. Evidence showed that when a ship arrived in Belfast Lough outside the borough limits carrying the yellow flag then the medical officer of health of the board of guardians took charge of the vessel and he had to get the assistance of the Belfast Corporation public health officials for disinfection, &c., and the expenses had to be borne by the districts outside the borough of Belfast who really had at present no arrangements to deal with such cases. There is no question but that it would be much wiser to have one central authority—the Public Health Department of the Belfast Corporation—to deal with the whole lough. The only opposition was from the local rural districts abutting on Belfast Lough who claimed that the Local Government Board had no jurisdiction to tax the districts in the neighbourhood of the lough except they formed a joint board, a course which would ensure taxation and representation going together. They objected to being taxed for the benefit of the port of Belfast. The evidence taken will be sent to the Local Government Board for it decision. The wise course would be to have one central authority vested in the city.

The Mater Infirmorum Hospital, Belfast.

This new hospital is to be opened by the Lord Mayor of Belfast on April 23rd, when addresses will be delivered by Cardinal Logue, the Marquis of Dufferin and Ava, the Righ Hon. W. J. Pirrie, and the Roman Catholic Bishop (Dr Henry). It is expected that the institution will be opene free from debt.

March 21st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Degree of Doctor of Biological Science.

BESIDES the degrees recognised by the State the universities of France can grant degrees exclusively scientific but which confer none of the rights or privileges belonging to the State degrees and which must in no case be declared as equivalent to them. Of the seven faculties of medicine in France four possess the right to present for a university doctorate as regards medicine. These four are Paris, Bordeaux, Lyons, and Nancy. This last body is not conten with her university powers and demands the right to presen for a degree persons who have shown their especial knowledge in biological science. The council of the University of Nancy has agreed to this proposition and accepted it at a special meeting on Feb 12th. The resolution has just been approved by the Minister of Public Instruction, and so, starting during the present scholastic year, the Faculty of Medicine at Nancy is authorised to present for the new degree, which is the first of the kind to exist in France. The testamurs (*attestations*) in the higher studies in biology which have to be submitted are three in number—one for anatomy, one for physiology, and one for microbiology. The subjects of study for each testamur are also three in number, two of them being compulsory and dealing with the special subject of the testamur, and the third being optional, which the candidate can choose from a given list. The subject must be approved by the professor and after this the sole test consists in the candidate showing that his knowledge of the question chosen is thoroughly up to-date (*mise au point*). The written dissertation must be accompanied by specimens or illustrations bearing on the question, such as sections, diagrams, charts, or anatomical preparations. A candidate who has gained his testamur may present himself for the degree of Doctor in biological science. A thesis is also required showing personal acquaintance with the facts of biological science, which thesis must be defended in public. Before the defence the manuscript must be submitted to the different members of the jury who will decide as to its merits. The public defence of the thesis follows upon this previous test

The Sanitary Condition of Paris.

The question of a supply of wholesome drinking-wate continues to occupy the attention of the sanitary authoritie and has also come up in Parliament The recent epidemic in the schools have furnished Dr. Treille, a senator, with a opportunity for asking the Minister of Public Instruction question. Dr. Treille said that he was not in sympat with the modern theories of the microbial origin of t disease. Water was not the principal cause of infection and typhoid fever was due to the insanitary condition of old buildings and to disturbances of the earth owing to the works recently carried out for repairing the drains and sewers. The Minister, naturally enough, replied that the organisation of the schools was perfect; they were supplied with spring water for drinking and the water of the Seine was only used for washing down the yards. The committee charged with the inquiry into the causes of the epidemic have unanimously agreed that the contamination of the drinking-water mains arose from an accidental communication having been established between them and the mains conveying the Seine water. Since an order was given for all drinking-water to be boiled the epidemic has disappeared. The remarkable views of Dr. Treille are a strange confirmation of the blind confidence which the city engineers have in the water which they supply, whence it follows that they are in the habit of saying, whenever an epidemic breaks out, that the fault rests anywhere but with them. Dr. Thoinot, the secretary of the Consultative Committee of Hygiene, has been put in disgrace for having, in a communication made to the Academy, too freely made public the causes of the original insanitary conditions which go far to render useless the great sacrifices which the city of Paris has made to procure a really wholesome supply of drinking-water. One of Dr. Thoinot's pupils, Dr. Arago, has just presented a thesis for the degree of Doctor of Medicine, called "The Avre, the Vanne, and the Dhuys: a Study in Parisian Sanitation," which he defended before the Faculty of Medicine at Paris and which has excited much interest. In this thesis he agrees with Dr. Thoinot and says that all water supplied by the city should be boiled before using for drinking or in the preparation of food. This statement, which is not very re-assuring, has been reproduced widely in the lay press. The Assistance Publique is very busy preparing for hospital accommodation for cases of infectious diseases in view of a possible epidemic and also in view of the increased number of cases of illness to which the Exhibition, as is always the case, will give rise. It is intended to build a new infectious hospital at Ivry just outside Paris close to the present infectious hospital, but as this cannot be ready for a long time the Assistance Publique will for this year content itself with enlarging and improving the present temporary hospital at Aubervilliers. The existing huts will be restored and two new wards, each containing 24 beds, will be erected. The total cost will be 71,000 francs and the Assistance Publique will thus have 418 new beds for infectious diseases at its disposal, a number which after all is too little for the inevitable rise in the sick rate which the Exhibition is sure to bring about.

Spitting on the Pavement.

In my letter in THE LANCET of Jan. 6th, at page 68, I mentioned that the Municipal Council of Paris had decided to put up enamelled metal notices in the chief streets requesting the public, with a view to avoiding the dissemination of infectious disease, to refrain from spitting on the pavement. This decision was taken on the initiative of M. Fortin. The question came up again at the meeting of the council held on March 16th, when it was decided that instead of enamelled plaques posters should be provided lettered as follows: "In the interests of public health and to avoid the dissemination of tuberculosis you are requested not to spit on the ground." These posters will be put up in the streets and in the public gardens. The railway and omnibus companies are also to be approached with a view to these posters being put up in the stations, waiting-rooms, railway-carriages, tramcars, omnibuses, and other vehicles. Measures are also to be taken to have both the roads and footways washed down.

March 20th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

International Hygiene: The Lazzaretto of Mogador.

ITALIAN diplomacy has scored a point in the interests of international hygiene. The island of Mogador, opposite the seaport of that name on the Atlantic littoral of Morocco, had for some time been used as a lazzaretto for the pilgrims of the Sultanate who, on their return from Mecca, had to be subjected to quarantine. The use of the island for that purpose, however, was never agreeable to the Court of Fez which, through the Government of Tangier, adopted something more than a policy of "pin-pricks" towards the Powers at whose instance the lazzaretto was maintained. Matters, indeed, had come to this pass that, on the expiry of the last quarantine, the Governor of Tangier ordered the physicians and agents of the "Council of International Sanitation" to be expelled the island and, at the same time, destroyed the buildings and huts in connexion with the lazzaretto. The situation had become very serious when, on the part of the "Council," the Italian envoy at Tangier, the Commendatore Malmusi, undertook to re-establish the *status quo antea*. A better intermediary could not have been found, for Signor Malmusi is eminently a *persona grata* at the court of the Sultan, besides possessing much diplomatic experience and tact. He has succeeded accordingly, and has just announced to the Consulta (Foreign Office) that all difficulties have been amicably resolved; that the lazzaretto will be re-constituted on the old lines; that the agents of the "Council" will remain unmolested at their posts; and that for purposes of quarantine and sanitary interests in general the island of Mogador is henceforth international property.

In Memory of Italy's Surgeons fallen in Battle.

This afternoon witnessed a touching ceremony at the Army Medical Hospital on the Cœlian Hill. It was the unveiling in the *atrium* of the hospital of a memorial tablet inscribed with the names of 35 surgeons, military and naval, who had fallen in action under the Italian colours from 1848 to 1896. The King and Queen were present, accompanied by the ladies of honour and the officers attached to the royal person, by the Prime Minister (General Pelloux) and members of the Government and both Houses of Parliament, and by a large attendance of the academic and clinical professoriate as well as consultants, general practitioners, and leading citizens. The tablet, designed by the sculptor Tripisciano, is very simple but artistically effective, presenting in bas-relief an altar on which the figure of Italy lays a laurel branch, while a guardian angel bearing aloft a palm of victory and leaning on a lion which holds Italy's banner in its paws, keeps watch over the altar consecrated to the fallen. The tablet, surmounted by an eagle supporting the subalpine arms in its claws, has the following inscription in golden letters: "To commemorate the medical officers who fell in the campaigns of the Crimea, of Italy, and of Africa." Then come in chronological series the officers' names. The veil having been withdrawn Major General Givogre of the army medical staff, who is also director of the hospital, in a few well-chosen words detailed the circumstances in which the gallant officers had met their death, and he was followed by Dr. Paolo Postemski, professor of pathology and clinical surgery at the Sapienza, who, speaking in the name of the Red Cross, made touching allusion to those of the organisation who had fallen, two of them having been favourite pupils of his own. Colonel Chiaiso of the medical staff and Colonel Ferrero di Cavallerleone of the combatant army spoke eloquently for their respective branches of the service, after which their Majesties, having warmly congratulated the sculptor and having cordially received those relatives of the fallen who were in attendance, went round the hospital, pausing repeatedly at the bedsides and addressing consolatory words to the patients. The whole ceremony, which was highly successful, forms the closing chapter of a story of professional skill, courage, and devotion to duty in the highest degree honourable to Italy—a story which (for the African campaign at least) has been brilliantly told by the army surgeon, Colonel Panara, in his book "Sulla Operosità del Corpo Sanitario Italiano durante la Campagna d'Africa (1896)."

Professor Robert Koch in Italy.

In May next Professor Koch, *en route* through Turin to the scene of his studies in malaria, will repair to Salsomaggiore to investigate the treatment of tuberculosis with inhalations from its richly iodised hot springs as an adjunct to his own lymph. Turin is preparing to give the illustrious bacteriologist a festive greeting and is already organising a committee for the purpose of which the president is the Senator Dr. Edoardo Maragliano, professor of clinical medicine in the Genoese school, and himself a distinguished worker in the serotherapy of tuberculosis.

March 19th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Report of the State Board of Charities of New York State.

THE thirty-third annual report of the State Board of Charities has recently been made to the New York State Legislature. Fully 100 Bills affecting directly or indirectly the charities of the State were introduced during the four months of the legislative session. The most important of those passed was undoubtedly the law as to dispensaries. In 1897 and again in 1898 unsuccessful attempts were made by a number of medical societies to obtain the adoption of a measure so governing the operation of dispensaries as to restrict free treatment at these charities to the poor. The Dispensary Act which has now become law will in all respects fulfil this object. The Board reports the number and classification of beneficiaries in institutions subject to its supervision October, 1899, to be as follows: aged and friendless persons, 7392; inmates of almshouse institutions, 11,251; blind in almshouses, 341; blind in other institutions, 414; deaf in almshouses, 94; deaf in other institutions, 1548; dependent children, 31,218; disabled soldiers and sailors, 1611; epileptics in almshouses, 316; epileptics in Craig Colony, 378; hospital patients, 8223; idiotic and feeble-minded in almshouses, 1153; idiotic and feeble-minded in State institutions, 1303; juvenile offenders, 3501; inmates of reformatories, 1868; making a total of 70,611. During the fiscal year ending Sept. 30th, 1899, the total number of State poor provided for was 2135 as against 1913 during the previous year. During the fiscal year ending Sept. 30th, 1899, 88 alien poor who had been found in almshouses, asylums, hospitals, and other charitable institutions in New York State were removed to their homes in different countries of Europe. The total number of Indian poor provided for in almshouses during the year was 15. The Board report very favourably on the plan which was introduced during the past year of placing destitute infants as far as possible with private families rather than massing them together in one large institution. The death-rate in the infants' asylum at Randall's Island was in 1898 96 per cent., in 1899 the mortality was considerably lower, but the fact has been over and over again conclusively proved that the more humane method of rearing children is to keep them apart.

Uniformity in the Standard of Medical Education in the United States.

The lack of uniformity in the standard of medical education in the various States of the American Union is becoming a matter of such grave importance that at length it appears as if really serious efforts will be put forth to place the laws regulating medical practice on a proper basis. Movements have been set on foot in Michigan and New Jersey with this object in view and there are signs that other States will follow suit. Of course, the question of inter-State reciprocity cannot be considered until the standards of academic and medical education shall be substantially the same in all States So long as this uniformity is not attained in the different States just so long will general reciprocity be impossible. It is hoped that the problem may be solved at the meeting of the National Confederation of State Examining and Licensing Boards which will take place at Atlantic city in July. This body is composed of the representatives of the examining boards of the different States, and any decision which might be arrived at by its members would be final. At any rate, the present anomalous state of affairs with regard to the laws ruling medical practice in the United States has become almost unbearable, and the fact is evident that remedial measures must ere long be taken. In connexion with inter-State reciprocity, some disgruntled medical men who were desirous to practise in New York State but who objected to undergo the test examination required by that State before being permitted to do so raised recently a rather nice point in constitutional law. These gentlemen contended that no State had the right to insist upon a further examination from men who already held a regular degree in medicine obtained in another State. Their argument was that such a proceeding was constitutionally illegal and at variance with certain sections of the Constitution of the United States, and especially of one section which says: "The citizens of each State shall be entitled to all privileges and immunities of citizens in the several States." It has, however, been shown that this belief is founded upon a misconception of the powers of the individual States to make laws. When the Union was formed the States composing it by no means gave up their sovereign powers but retained many of them, among which was the right to make police laws, including the laws regulating the practice of medicine. It would, indeed, be in a high degree unfair to the men who have taken their degrees in medicine in New York State (where a high standard of medical education is insisted upon) if graduates in medicine from other States (in some of which an extremely low standard is required) were allowed to compete with them on equal terms. Nevertheless, the fact has been clearly proved that general uniformity in medical education throughout the United States is badly needed.

Wards for the Insane in General Hospitals.

In 1889 an Act termed the "State Care Act" was passed by the New York Legislature the provisions of which enacted that the State of New York should assume the charge of all pauper patients legally adjudged insane and that the State should be divided into 11 districts, in each of which a hospital is situated for the treatment of the patients living in the locality. This arrangement has now been in working order for several years and has on the whole fulfilled its object admirably, but in the plan there remains one serious defect. When the patient has been declared insane and awaits removal to the State hospital no statutory requirement exists as to management in the interval. In New York county, King's county, and Erie county "detention" or "reception" buildings have been provided in connexion with existing hospitals, but in the rest of the State the insane person is either cared for by friends or placed in gaol. As may be imagined this method of treatment is not conducive to the recovery of the patient but, on the contrary, has had in many instances results disastrous to life. Bellevue Hospital, New York city, was the first to establish reception wards for the insane and the experience gained there has been at once instructive and most satisfactory. The improvement effected in the case of many patients has been so marked that subsequent transfer has been found to be unnecessary. Albany has now decided to follow this example, or rather to improve upon it, and a special pavilion for the insane is to be erected in connexion with the general hospital in that city. The *Albany Medical Annals*, referring to the matter, says: "It is anticipated that cases of acute delirium, alcoholic or otherwise, may be by these means protected from dangerous delays and neglect, that doubtful cases may be observed during consideration of the proper disposition to be made, and that commitments may be carefully and judiciously considered to the advantage both of the patient and the State institution to which he may be sent" The outcome of the Albany experiment will be watched with great interest throughout the United States. It is the opinion of many noted American alienists that the treatment of acute cases of insanity has up to the present been conducted upon an erroneous system and that for such cases special hospitals or special pavilions in connexion with general hospitals should be established.

A Proposed Leper Colony.

Dr. A. S. Ashmead, the well-known leprologist, recommends the establishment of a leper colony in the United States. Dr. Ashmead declares that the United States is the dumping-ground for the lepers of the whole earth and says that the condition of the laws of the country is an encouragement to lepers to come from everywhere. It is said that Dr. Ashmead has drafted a law which is to be submitted to Congress and which is intended to protect the United States from lepers. The said law provides for a commission on leprosy, to be selected by the President and to hold office for five years, and for a tract of land of 640 acres to be set aside as a national leper home in Yellowstone Park or elsewhere at a distance from the coast. The Bill also provides for an appropriation of $50,000 (£10,000) for buildings and makes it unlawful for any board of health to permit a leper to remain in their jurisdiction except in isolation. Indigent or helpless lepers are to be committed to this home. The Bill furthermore provides that it shall be unlawful for any steamship or railroad company to bring to the United States any leper or accept any emigrant from a country where leprosy is common without a special certificate from the Government Board of Health of that country countersigned by the United States consul and a

United States Marine Hospital surgeon attached to the consulate at the port of embarkation. The United States Marine Hospital Service is to have charge of the leper home. Dr. Ashmead is one of that large band of leprologists who firmly believe in the contagiousness of leprosy, and consequently he is in favour of total isolation. That isolation is the best means of treating this loathsome disease will probably be the opinion of even those who do not take extreme views as to its contagiousness. It is undoubtedly true that there are a number of lepers at large in the United States—in fact, it has been recently asserted that there are 100 lepers in New York city. Therefore a Bill such as is proposed by Dr. Ashmead would be to the benefit of the general public. The suggestion has been made recently that the lepers in the United States should be shipped to Honolulu and placed in the leper colony there.

March 14th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Australasian Association for the Advancement of Science.

THE meeting of the Australasian Association for the Advancement of Science was held this year in Melbourne under the presidency of Mr. R. L. J. Ellery, F.R.S., C.M.G., late Government Astronomer. In the section for Sanitary Science and Hygiene some interesting papers were read. Dr. W. W. R. Love of Brisbane was to have presided over the section and given an address, but at the last moment was unable to attend; and at very short notice Dr. J. Jamieson, health officer of the city of Melbourne, took his place, and dealt in an able manner with the three diseases always present in Melbourne—typhoid fever, tuberculosis, and diphtheria. He said that typhoid fever had long been unduly prevalent in Victoria, and particularly in Melbourne. There was some reason, if not full excuse, for this condition of affairs, at least as regards Melbourne, in the fact that the metropolis of the colony had grown rapidly into a populous city, spread over a large area, with such fouling of the soil as must inevitably result where drainage facilities were defective. It was only about ten years ago since a comprehensive scheme for the drainage of Melbourne was planned, and even now only a small proportion of the houses had been connected with the sewers. He had always held that this foulness of the soil had much to do with the persistent prevalence of this typically filth disease. There was good reason to believe that the prevalence of typhoid fever in Adelaide and Sydney had been greatly reduced by the extension of drainage operations and the consequent purification of the soil around dwellings. He had noticed that the periodicity of prevalence of typhoid fever in Melbourne was apparently about every four years, but could find no satisfactory hypothesis to account for it. Though time alone could supply further evidence the experience of other parts of the world justified the confident hope that before many more years had elapsed typhoid fever as a cause of death would stand constantly at or below the lowest level which it had hitherto occasionally reached. In this colony, as also in Great Britain, tuberculosis caused about twice as many deaths year by year as all the well-known epidemic diseases taken together. It was now clear from the results of observation and experiment that unhealthy surroundings and contagion were the real causes of the occurrence of the disease in most cases, although it could not be said that heredity counted for nothing in calculating the liability to the disease. The firm assurance had been reached that tuberculosis in all its forms was a preventable disease and also that in a large proportion of cases it was curable if proper treatment was instituted. With regard to diphtheria evidence satisfactory to the vast majority of observers had been supplied that by the injection of the antitoxin many cases could be brought to recovery which would otherwise have proved fatal.—Dr. S. S. Argyle contributed a paper on the Milk-supply of Melbourne, which he characterised as one of the worst in the world. Practically all the supply was derived from 1510 dairymen who all delivered the milk by the open can method and without protection from the sun or street dust. The dairy farms were within a radius of 30 miles, and the milk from these was at least 12 hours old before it reached the consumer, and in some cases milk unsold on Wednesday afternoon was kept on ice till the following Sunday. He estimated that 500 infant lives per annum could be saved if the milk supply was satisfactory. Municipal inspection of drains was infrequent and perfunctory and the railway arrangements for carrying and storing milk were grossly unsuitable. Dr. Argyle gave results of bacteriological investigations demonstrating the extraordinary growth of pathogenic organisms in milk under the local conditions. He advocated the system of milk-supply adopted in Copenhagen.—Dr. M. Crivelli read a paper on Alcoholism, distinguishing between the alcoholic who gradually saturated all his tissues without getting drunk and the dipsomaniac who had intermittent bouts of drinking. Both, however, were degenerates, the victims of cerebral disease. Dr. Crivelli maintained that every dipsomaniac was neurasthenic, and chiefly so by heredity. As regards treatment, reliance was placed on two remedies, in addition to special regimen. These were large doses of strychnine, hypodermically injected, and injections of ordinary blood serum—a special serum from an alcoholised animal being no more beneficial than that from any other animal or than artificial serum consisting of a sterilised solution of chloride phosphate and sulphate of sodium, which Dr. Crivelli had used with success.

Mr. A. M. Henderson, M.C.E., read a paper entitled a Comparison of the Drainage Details of Melbourne, Sydney, and Adelaide, in which he criticised adversely some of the details of the Melbourne scheme, especially the arrangements for drain-traps for cellars and the cost of the inside plumbing work and ventilation. "The system followed throughout the three colonies was the English one, under which the air of the drain was kept outside the buildings by disconnected traps, except in the case of closets. We might expect that a cheaper class of inside plumbing and less ventilation would be safe with that system but it appeared that we would have the extra cost of American plumbing added to the cost of English disconnexion." Under the arrangements for cellars by a recent notice of the Board of Works subsoil drainage will be practically stopped and one of the main objects of the great expenditure in deep drainage frustrated. Previous to this notice traps with reflux valves and in some cases silt-traps have been allowed, as in Sydney and Adelaide.

In the section of Mental Science and Education the President, Dr. W. L. Cleland, superintendent of the Parkside Lunatic Asylum, Adelaide, gave an address on the Anatomy of Mind as Bearing on Education. He emphasised the connexion between mental science and a teacher's qualifications. He would allow no one to enter the teaching profession who was ignorant of what was known anatomically, physiologically, and philosophically respecting a child's mind. The brain was not, he said, one uniform whole, but must be looked upon as consisting of a number of specialised organs or structures. Dr. Cleland then proceeded to describe in detail the action of these specialised organs and their relation to the rest of the child's anatomy. Dealing with the effects of fatigue, he urged that all attempts at teaching should at once be discontinued upon a child showing any of the signs of mental fatigue or exhaustion. If the period of rest for cell recuperation was curtailed an irritable condition was set up, as a result of malnutrition, which might become habitual. Dividing the period of a child's development into three divisions Dr. Cleland would have the education in the first, the pre-school division, devoted to the cultivation of the articulate capacity, to connecting names with various objects, and to stimulating observation of surrounding persons and things. In the second division he would allow the introduction of education in the more technical sense. The characteristic attitude of the teacher at this stage would be one of dogmatic insistence. In the third division the child was supposed to have passed to the age of reason, and the teacher to assume the role of guide, philosopher, and friend. Dogmatism would be now out of place and appeals could be made to abstract propositions and generalisations. Dr. Cleland's conclusions were, if education was to be conducted on the lines of brain growth and with due regard to developing anatomy: (1) the necessity for an abundance of nutriment out of which to elaborate nerve force; (2) the necessity that there should be a cultivation suited to each period of growth; and (3) the necessity for a study of the individual potentialities of each pupil, so as not to expect the unattainable in one case or repress the possibilities in another.

In the same section a paper was read by Dr. R. R. Stawell on the problem of the State Education of Children

Physically Afflicted or Mentally Impaired. After briefly sketching the history of the movement for the State education of the blind, deaf, and otherwise defective children in England and elsewhere, he pointed out that there was a class of feeble-minded children as distinguished from imbeciles or idiots. The former might be trained so as to become serviceable citizens; the latter could only be made as happy as possible under the sad conditions of their lives. The physical conditions of feeble-mindedness needed more exact investigation. All scholars below or above the average should be examined by an expert. It was estimated that 1 per cent. of the children of the school-going age were feeble-minded and needed special provision. In Victoria 188,359 children between six and 13 years of age were enrolled in schools, about 10,000 being unaccounted for. There were probably 2000 children, therefore, in Victoria who needed special educational assistance and who were at present totally neglected. A conference should be held between inspectors of schools and medical experts to determine a standard and methods of examination and there should be a house-to-house census of children of school age. The system of instruction should be such as had proved effective in the case of imbeciles and a competent instructor should be imported from England. The teachers' training should include general kindergarten methods, physiology and school hygiene, gymnastics on some rational method, voice production and articulation, "Sloyd" and other manual work, and some months' practical instruction. Special classes could be formed at once within the metropolitan area with advantage on the lines recommended by the late British Royal Commission and homes should be opened for the reception of such children in the neighbourhood of the classes.

Criminology from a Medical Standpoint was treated by Dr. J. V. M'Creery, medical superintendent of the Kew Asylum, in a thoughtful paper in which he pointed out that much difficulty and confusion were caused by the present practice of trying to force all persons accused of crime into one of two groups—to make them either fully responsible or quite irresponsible for their actions. Such a division did not naturally exist and any real reform must be based on a more perfect classification. Much of the conflict of medical evidence now so often heard in their courts when the question of insanity arose was due to the confounding of insanity and responsibility and the arbitrary line drawn between this latter and total irresponsibility. The non-natural view of insanity generally taken by the legal mind was not favourable to the full and calm consideration of the causes which led to crime being committed. The difficulties were increased by the method of each side calling its own expert witnesses, and as the object of the lawyer was to make out the best case possible for his own side the medical witnesses were often forced into a wrong position and to take opposite standpoints even when no fundamental difference existed between them. Persons found not guilty on the ground of insanity were detained in a gaol or asylum at his Excellency's pleasure, and under the old restricted view of criminal insanity little or no inconvenience was caused by this arrangement. But this term was ever growing wider and some more definite system of dealing with these unfortunates seemed needed. Some of these cases were sane at the time of the trial; others became so afterwards. Naturally efforts were made to procure the discharge of persons whom the law did not hold responsible for their acts and who afterwards became sane. Not only, however, might there be danger to the community in permitting such persons to be at large, but there appeared to be a growing tendency for criminals to hope for a lenient view being taken of their deeds by shielding themselves behind the plea of insanity. There could be, he believed, no hard-and-fast rule in dealing with criminals. Each case required careful study and such methods of treatment as might best promise improvement to the individual and safety to the community. To do this the matter must be dealt with by the combined wisdom of the lawyer and the medical man and the common sense of the laymen. The present system did not reform many criminals or in any satisfactory manner protect society. Until they faced and grappled with the real facts of the causes of crime little advance could be expected.

In the section of Economics Mr. A. O. Powys of St. Kilda read a mathematical paper which dealt with the Annual Probability of Death from Cancer at Every Age of Male and Female Life in New South Wales, Victoria, England and Wales, and Scotland. The "crude probabilities" derived from the annual number of deaths and the population according to ages were adjusted upon Professor Karl Pearson's theory of skew curves. The equations to such curves were given, together with the ages of greatest probability and the intensity. Thus, amongst males in Victoria in 1881 the maximum death-rate was 3·93 per 1000 at the age of 76 years, whilst in 1895 the maximum was 6·43 per 1000 at the age of 77 years. Amongst females the corresponding values were 3·80 at the age of 70 years and 6·12 at the age of 74 years respectively. The death-rate, said Mr. Powys, did not afford a true gauge of the ravages of cancer unless between communities of like "age constitution," as the death-rate from cancer was very small at ages under 35 or 40 years. After placing the several communities upon the same basis as regards age constitution it was found that cancer was more fatal in Scotland—an essentially non-meat-eating community—than in the Australian colonies, where the inhabitants are essentially meat-eaters. This should prove that increased meat-eating was not responsible for the increase in the cancer death-rate. Mr. Powys agreed with the view of Dr. Woods Hutchinson that some part of the increase of cancer was due to the fact that, "to use a Hibernicism, more people are living long enough to die of it." Using the adjusted cancer death-rates in conjunction with a life table it appeared that in Great Britain one out of every 22 males born dies ultimately from cancer, and of those who survive to the age of 40 years one in every 14. In Australia one out of every 19 males born, and one out of every 13½ who survive to the age of 40 years, so die.

Obituary.

JOHN CADWALADR WILLIAMS, M.B., C.M. EDIN., M.R.C.S. ENG., L.R.C.P. LOND.

THE death is recorded at the early age of 31 years of Dr. John Cadwaladr Williams of Grange-road West, Middlesboro', which took place at his home, Brynymor, Penygroes, Carnarvonshire, on March 12th. The sudden death of his father, the Rev. J. J. Williams, on March 1st had brought him home and being in indifferent health he contracted a chill at the funeral which resulted in pneumonia. Dr. Williams was educated at Edinburgh University and the Royal College of Surgeons of Edinburgh, gaining the silver medal in anatomy and holding the post of demonstrator of anatomy at the latter school. He took the degrees of M.B. and C.M. Edin. in 1891. Subsequently he became a ship surgeon and on his return he continued his studies at Guy's Hospital, London, and took the M.R.C.S. Eng. and L.R.C.P. Lond. in 1897. Shortly afterwards he settled down in Middlesboro' as partner with Dr. W. J. Williams, Grange-road West, where he rapidly gained the confidence of his patients and by his kind, thoroughly upright, and honourable disposition formed a large circle of friends who mourn his loss. He also held the office of public vaccinator for the Middlesboro' district.

ALLAN McLEAN, M.D., C.M., L.R.C.S., L.M. EDIN., J.P.,

LIEUTENANT-COLONEL COMMANDING 1ST DORSET VOLUNTEER ARTILLERY.

THE death is announced at his residence in Weymouth of Lieutenant-Colonel McLean, M.D. Edin., the commanding officer of the 1st Dorset Volunteer Artillery. The deceased, who received his medical education at Edinburgh University, graduated M.B. and C.M. in 1868 and in the same year took the qualifications of L.R.C.S. and L.M. Edin. He was admitted to the M.D. degree in 1889. Dr. McLean was one of the leading practitioners in Dorset, being formerly medical officer of health of the Isle of Portland and for 19 years physician to the Royal Portland Dispensary. In 1864 the deceased received a commission in the Edinburgh University Rifles and since then had taken a very keen interest in the volunteer movement. In 1885 he succeeded Colonel Elliott as commanding officer of the 1st Dorset Volunteer Artillery, and the present efficiency of the corps is largely due to Dr. McLean's efforts. The deceased was a Justice of the Peace for the county of Dorset and an energetic Freemason, well known in the province of Dorset. Dr. McLean had lately been in failing health, but his death came somewhat suddenly.

Medical News.

Foreign University Intelligence.—*Cracow:* Dr. S. Ciechanowski has been appointed Extraordinary Professor of Pathological Anatomy.—*Bologna:* Dr. Cervesato of Padua has been appointed Professor of Children's Diseases.—*Genoa:* Dr. Rudolf Weber has been appointed to the chair of Mental Diseases in succession to Dr. J. Martini, resigned.—*Jassy:* Dr. C. Juvara has been appointed Professor of Surgical Anatomy.—*Leipsic:* Dr. Felix Marchand of Marburg has been appointed to the chair of Pathological Anatomy in succession to the late Dr. Birch-Hirschfeld.—*Marburg:* Dr. Hugo Ribbert of Zürich has been appointed to the chair of Pathological Anatomy in succession to Professor F. Marchand who goes to Leipsic. He is the author of a manual of pathological histology and a work on the historical development of the theory of disease.—*New York Polyclinic and Hospital:* Dr. R. O. Born has been appointed Professor of Ophthalmology.—*St. Petersburg:* Dr. Skorichenko has been promoted to the ordinary Professorship of the History of Medicine and Dr. Kholodovski to the ordinary Professorship of Comparative Anatomy. Dr. Magawly, Director of the University Ophthalmic Clinic, who was a pupil of Albrecht von Graefe and assisted in introducing modern ophthalmic surgery into Russia, is about to retire.—*Turin:* Dr. A. Carle has been promoted to the ordinary Professorship of Surgical Pathology.

Prudential Assurance Company, Limited.—The continuous prosperity of this long-established company is clearly shown by the recently published accounts and balance-sheets for 1899. In the ordinary branch the number of policies issued during the year was 65,470, assuring the sum of £6,355,850 and producing a new annual premium income of £352,003. The premiums received during the year were £3,144,464, being an increase of £176,963 over the year 1898 The claims of the year amounted to £1,225,906. The number of deaths was 5899 and 3963 endowment assurances matured. The number of policies in force at the end of the year was 570,414. In the industrial branch the premiums received during the year were £5,168,958, being an increase of £208,202. The claims of the year amounted to £2,059,340. The number of deaths was 209,807 and 2239 endowment assurances matured. The number of free policies granted during the year to those policy-holders of five years' standing who desired to discontinue their payments was 72,611, the number in force being 663,250. The number of free policies which became claims during the year was 14,533 The total number of policies in force at the end of the year was 13,433,785; their average duration exceeded 8¾ years. The assets of the company in both branches were £36 832,059, being an increase of £3,232,351 over those of 1898.

Eczema at the Leicester Cottage Homes.—Since the opening of the Leicester Cottage Homes in 1884 there have been many cases of eczema of varying degrees of severity and, in accordance with the request of the Local Government Board, the guardians instructed the medical officer of the homes (Mr. Richard Steele) to make a report as to the water supply as it affected the health of the children. In his report Mr. Steele said the children at the homes as a rule were admitted very young and had a healthy look considering the nature of their bringing up and of the surroundings from which they came. Some of those who had never suffered previously from any skin affection developed, soon after admission, a certain degree of eczema in various parts of the body, particularly the scalp. He was strongly of opinion that the hardness of the drinking-water was largely answerable for the condition of eczema which was too prevalent there. At a meeting recently held the guardians reported that on the receipt of this report they forwarded samples of water drawn from three of the wells to Mr. S F. Burford, analyst. The latter reported that the water from one well was badly polluted with animal organic matter and was unfit for drinking or domestic use, showing in addition to other foreign matter 77 grains of solid matter per gallon, 6 09 grains of chlorine, and 2 08 grains of nitrogen as nitrates. The water from another well was even worse, the water being slightly turbid and containing per gallon 9 49 grains of chlorine, 179 9 grains of solid matter, and 118 degrees of hardness; ammonia was also present. It was not fit for drinking or for domestic purposes. Having regard to these unsatisfactory reports the board decided to seek for other sources of water-supply.

Bristol Medical Dramatic Club.—The Bristol Medical Dramatic Club will give a performance of J. M. Barrie's comedy *The Professor's Love Story* at the All Saints' Hall, Clifton, on April 24th, 25th, 26th, 27th, and 28th, at 8 P.M., in aid of the funds of the Royal Infirmary and General Hospital.

Appointment of a Medical Officer of Health.—At the meeting of the St. Austell (Cornwall) Urban District Council held on March 13th, after a considerable discussion, Mr. William Mason, L.R C P. & S. Edin., was appointed medical officer of health for life, an amendment to make the appointment for three years only being defeated by seven votes to four.

Vaccination Prosecutions.—A number of vaccination defaulters were summoned at Frome (Somerset) on March 15th. Mr. Schultess Young, who defended, took the objection that the guardians must direct prosecutions under Section 29 of the Act and that the wrong section had been taken. After an argument the bench of magistrates dismissed all the cases.

Western Counties Veterinary Medical Association.—The annual meeting of this association was held at Exeter on March 15th under the presidency of Mr. Penhall. Professor Stewart Stockman of the Royal Dick College, Edinburgh, read an interesting paper on the Method of Infection in Black Quarter, after which a discussion followed. Mr. Bond of Plymouth was elected president for the ensuing year.

Lunacy in Dorsetshire.—At the annual meeting of the Dorset County Council held at Dorchester on March 13th under the presidency of Lord Dorchester it was reported by the Asylums Committee that 1899 had been the most prosperous year on record as regarded profits from out-county and private patients and £2000 had been handed over to the county exchequer. The number of pauper patients for the first time for some years showed a decrease.

Bristol Medical Missionary Society.—The twenty eighth annual meeting of this society was held on March 13th under the presidency of Mr. J. Storrs Fry. The honorary secretary stated that 7535 patients had been under treatment during 1899; their attendances numbered 22,587. 1833 patients had been attended at their homes. The financial report showed that the adverse balance of 1898 had been slightly reduced by a legacy received, but the expenditure exceeded the income from subscriptions and donations.

Literary Intelligence.—The following books are in the press and will be published by Messrs. J. and A. Churchill at an early date:—"The Clinical Examination of Urine, with an Atlas of Urinary Deposits," including 41 original plates (mostly coloured), by Dr. Lindley Scott; "A Treatise on Diseases of the Ear," second edition, by Mr. Mark Hovell, aural surgeon to the London Hospital; new editions of Dr. Tom Robinson's books entitled, "The Diagnosis and Treatment of Syphilis" and "On Eczema"; the third edition of Clowes' and Coleman's "Elementary Practical Chemistry"; and "Chemistry, An Exact Mechanical Philosophy," by Fred. G. Edwards, inventor of atomic models.

Bristol General Hospital.—The annual meeting of governors and friends of this institution was held on March 12th under the presidency of Mr. W. Proctor Baker. The medical report stated that 2023 in-patients had been admitted during 1899, against 1393 in the previous year; the out-patients numbered 29,287, against 27,876 in 1898. The financial report showed that if it had not been for utilised legacies there would have been a deficit of £2300. The workpeople's contributions amounted to £2041. The ordinary finances showed an increase over 1898, but this was accounted for by the larger amount of donations, including £1000 from Sir G. Edwards and a similar sum from an anonymous donor. It was stated that the following scholarships had been awarded: Clarke surgical scholarship of £15 to Mr. R. G. Johnson; Sanders scholarship of £22 10*s.* to Mr. R. G. Johnson; Lady Haberfield prize of £29 9*s.* 8*d.* to Mr. L. W. Morris; Martyn memorial scholarships—£10 to Mr. T. Aubrey and £5 each to Mr. R. G. Johnson and Mr. L. A. Moore.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Accounts of the General Medical Council.

ON March 16th returns of receipts and expenditure of the General Medical Council and of the Branch Councils for England, Scotland, and Ireland, also receipts and expenditure of the Dental Registration Fund for the year 1899 were laid on the table of the House of Lords.

The Midwives Bill.

The consideration of the Midwives' Bill by the Standing Committee on Law begins to-day, Friday (March 23rd). Another step in the progress of the measure was marked on Wednesday, March 21st, when notice was given of a motion to authorise the payment out of moneys to be provided by Parliament of such expenses as the General Medical Council may incur in the administration of the proposed legislation. A motion of this kind is necessary in connexion with all Bills which involve additional financial burdens. It is dealt with in committee of the whole House.

HOUSE OF COMMONS.

THURSDAY, MARCH 15TH.

The Sanitary Condition of Malta.

Mr. **STEVENSON** asked the Secretary of State for the Colonies whether he could now state the decision of Her Majesty's Government with regard to the advisability of holding a departmental or inter-departmental inquiry into the sanitary condition of the barracks, hospitals, and burial grounds at Malta with the object of improving the buildings occupied by the army and by naval officers and others in that island.—Mr. **CHAMBERLAIN** replied: The consideration of this subject has not yet been concluded, but as at present advised Her Majesty's Government do not perceive that any departmental inquiry will be required.

The Food of the Channel Fleet.

Mr. **MACNEILL** asked the First Lord of the Admiralty (1) whether he was aware that there was discontent among the crews of the Channel Fleet with respect to the quality and quantity of the food supplied to the ships, and that complaints with reference to the quality and quantity of the food were discountenanced by the officers and regarded as evidence of insubordination; and (2) whether he would direct an investigation independently conducted to be made as to whether the rations served on board Her Majesty's ships of the Channel Fleet were of the proper quality and quantity, and whether the Admiralty would direct the sale of provisions on board these ships to be discontinued, or provide that goods be sold at the canteens not at extortionate prices but at the prices at which similar goods were sold on shore.—Mr. **MACARTNEY** replied to the question saying: The answer to the first question is in the negative With regard to the second question I must refer the hon. member to the remarks made by me in the course of the debate in this House on Thursday last. The Managing Committee, which with two exceptions is composed of representatives of the men, should be competent to take precautions against extortionate prices being charged. As a matter of fact, it is understood that the goods sold in the canteens are retailed at a lower price than that at which they could be obtained by the men on shore.

The Wounded who have Returned to the Front.

Mr. **WINGFIELD DIGBY** asked the Under-Secretary of Sate for War whether he would give the actual or approximate number of those who had been returned wounded since the commencement of the war who were already cured of their wounds and back again at the front.—Mr. **WYNDHAM** I can give the figures up to Feb 2nd, which are as follows:—Wounded officers, 261; non-commissioned officers and men, 4583. Returned to duty officers, 67; non-commissioned officers and men, 705. These figures do not include casualties in Ladysmith and Kimberley since investment.

Dogs Regulation Bill.

Mr. **WALTER LONG**, President of the Board of Agriculture, introduced a Bill to amend the law relating to dogs. He explained that, the muzzling order having done its duty, there was now room for a more moderate measure, and this Bill would clear up doubts as to the law and enable local authorities to make by-laws.

Petroleum Bill.

A Bill was introduced by Mr. **URE** to raise the statutory flash-point of petroleum oil. Mr. Ure served on the Select Committee which inquired into the petroleum question and he introduced a Bill on the subject last session.

FRIDAY, MARCH 16TH.

Milk Prosecutions.

General **LAURIE** asked the President of the Local Government Board whether his attention had been called to the report of the public analyst to the Vestry of Paddington for the quarter ending Dec 25th, 1899, wherein it appeared that the magistrate at the Marylebone Police Court, in the case of a sample of butter containing 65 per cent. of margarine, imposed no fine but only costs of 12*s.* 6*d.*, and gave the same decision in another case where the sample contained 80 per cent. of margarine, and in another case where the so-called butter was entirely margarine imposed a fine of 10*s.* and 12*s.* 6*d.* costs; also in two other cases where a farmer had sent to the railway-station two churns of milk from which half the cream was deficient the summons was dismissed on the explanation that the milk from which these samples was taken was received at the farm dairy on the evening of each day, mixed in a large container, and left for the night, and that next day the churns were filled for transmission to London by means of a tap at the bottom of the container, no previous stirring up of the contents of the container taking place; whether it would be possible to issue a circular or otherwise to instruct magistrates having jurisdiction in such cases that when milk was left undisturbed the cream rose to the top, and hence the lower part of the milk did not contain its share of cream, which it should be considered had been removed from it, and that such milk was to be dealt with as adulterated; whether his attention had been further called to the fact that practically the same percentage of milk purchased at railway stations was adulterated as of milk purchased in town, thus showing it was not the retailer who was alone to blame; and whether it was possible in any way to assist local authorities who were doing all in their power and expending large amounts of money in endeavouring to carry out the law so as to protect the humbler consumers and who thus found their efforts discouraged.—Mr. **WALTER LONG**, President of the Board of Agriculture, replied, saying: I have seen the report to which my hon. and gallant friend refers, but the information at present at our disposal would scarcely justify the adoption of the course suggested. Our inspectors are, however, closely watching the administration of the Acts, in consultation with the local authorities concerned, and the representations of my hon. and gallant friend will be kept in view. I could not take upon myself to express an opinion as to the respective culpability of producers and retailers of milk so far as adulteration is concerned.

Death Certification.

Sir **WALTER FOSTER** asked the President of the Local Government Board whether his attention had been called to the frequency of complaints in coroners' courts respecting the signature and filling up of death certificates; and whether he would bring in a Bill to amend the law of death certification, as recommended by the Select Committee of 1893.—Mr. **T. W. RUSSELL**, on behalf of Mr. Chaplin, said: I am aware that complaints have been made of the kind referred to. The question is being considered, but I am afraid I cannot give the undertaking asked for by the hon. Member to bring in a Bill during this session.

Army Rejections for Bad Teeth.

Mr **WEIR** asked the Under-Secretary of State for War, seeing that the First Lord of the Admiralty recently stated that fully 25 per cent. of the recruits for the navy were rejected on account of bad teeth, would he state what percentage of the recruits for the army were rejected for this cause during the year ending Dec. 31st, 1899.—Mr. **WYNDHAM**: The percentage was 7·74 of the total number rejected, 2·5 of the total number presenting themselves.

The Treatment of Lunatics in Scotland.

Mr. **WEIR** asked the Lord Advocate if his attention had been called to the recommendations contained in the forty-first annual report of the General Board of Commissioners in Lunacy for Scotland to the effect that measures should be taken to give district lunacy boards permissive powers to provide accommodation for the poorer class of private patient and would he say what action it was proposed to take in the matter.—The **LORD ADVOCATE** replied: The answer to the first paragraph of the question is in the affirmative. The Secretary for Scotland does not propose to take any action at present.

The Vote for the Army Medical Establishment.

The House in Committee of Supply on the Army Estimates discussed at length the vote of £555,000 for the medical establishment and for medicines, &c., for the year to March 31st, 1901.

Dr. **FARQUHARSON** spoke of the conspicuous success of the Army Medical Department in South Africa. He thought he might put it as high as to say that this department had been the real success of the war. The more they heard of what was going on at the front the more they were filled with admiration for the pluck, devotion, and skill which had been displayed and the hard work which had been carried out by the officers of the Army Medical Department. The Mauser bullet was a humane missile and where it gave a fatal wound was a swift mode of taking life. But he could not speak in too severe terms of condemnation of the Boers for using soft-nosed bullets, the wounds from which, if he were to give details, would simply appal the Committee Sand and pebbles and every kind of external abomination were found in the wounds where they had been caused by this description of bullet. The hospital accommodation and nursing had both been excellent It had been found that the new system under which distinct and definite military rank was given to the medical officers had worked admirably, and he hoped to hear that the medical schools had done their best to provide a full and continuous flow of good candidates to fill up the ranks of the service. While the Government were proposing a large permanent increase to the army the increase in the number of medical officers was only six. They ought not to rely on any hand to-mouth system of employing civilians. He did not know that they would be very much longer able to obtain a sufficient number of eligible candidates for the present somewhat meagre pittance paid to men who had to go through six years of expensive and laborious preparation.

Mr. **PRICE** also spoke in terms of praise with regard to the work of the Army Medical Department in South Africa and suggested that greater inducements should be offered to medical men to join the service

Mr. **ARNOLD-FOSTER** asked for an explanation of the circumstance that large numbers of men on reaching South Africa had been sent to hospital.

Sir **WALTER FOSTER** said that many of the men sent out were suffering from chronic disease which ought to have been recognised. The number had so increased that temporary buildings for their accommodation had to be provided, the special hospital allocated for their reception having become full. The Royal Army Medical Corps had done their duty splendidly and shown great courage and devotion; but it had notoriously been weakened in numbers of recent years, and the pick of the corps having been sent to South Africa it was necessary to supplement those left at home by civilians. It might be that the errors made in passing men for the front were made by these temporary civilian substitutes. He regretted that a larger increase of the corps was not proposed. It would probably be necessary to offer an increase of pay in order to attract the best men. The War Office would have done better to spend money in this way than in lavish generosity to civilian surgeons who had gone to the front. It was perfectly right to send out Sir William MacCormac and Mr. Treves, who had rendered valuable services, but it was not necessary that everyone should be treated on the same terms as the most distinguished men in the profession. He believed that when one of the distinguished surgeons asked for an assistant the War Office rated the assistant on an equality with his principal and paid him on the scale of £5000 a year He also called attention to the prevalence which had been noticed especially at Ladysmith, of typhoid fever In the debates of last year it had been pointed out that Ladysmith was not a healthy place for a camp, that it was likely to be ravaged more or less by the prevalence of fever, and that its water-supply was not satisfactory Those criticisms had been amply verified by the terrible experience obtained in that position A similar condition of affairs had prevailed in various camps on the Modder river and elsewhere, and he hoped that the War Office would see that attention was paid not only to the surgical aspects of the war but to its sanitary aspects In some respects also our ambulances had not been found to be as useful as the ambulances of our enemies who had lighter carts He had been told by persons of experience that we had made a great mistake in having too heavy wagons The rule which ought to be followed was to obtain the lightest possible wagon for the roughest country, but that was a rule which had not been followed in building their ambulance carts for the use of the wounded He hoped that the debate might result in producing a greater amount of applications on the part of candidates for the Royal Army Medical Service He thought that the last examination was not as satisfactory as it should be in the number of applicants and he hoped that the medical schools throughout the country would take this matter up He thought that the suggested modification of the examination might be useful These men were now carefully examined under the supervision of the General Medical Council before they could obtain diplomas and consequently they ought to have an examination in a special direction in connexion with their future duties If this training were followed up by some experience, say, at Netley, six months before they were attached to any Army medical service the complete education necessary would be given, and if supplemented by opportunities to rub off the rust he thought a still more efficient Army Medical Corps would be produced than they had at present while affording inducements to men entering the profession to make that efficiency the object of their ambition

Colonel BLUNDELL recommended that for a certain period of time a medical officer should be attached to a regiment.

Mr WASON suggested that information should be published as to the results of inoculation against typhoid fever

Mr GEORGE WYNDHAM, Under Secretary of State for War replying on behalf of the War Office, said it was true that the committee could not pay too high a tribute to the fortitude, courage and efficiency of the medical officers which had been displayed. They were not exalted by the joy and intoxication of battle, they were sustained alone by their devotion to suffering humanity and this rendered their services *in his opinion all the more heroic* The medical schools in supplying candidates had fulfilled their part of the bargain, to which the department was the other party in allocating military rank. The result had been, he hoped, satisfactory to them as it had been to the army, but the department did not reap the whole results of such a change in the first or second year The next point raised was that the present numbers of the Royal Army Medical Corps were not adequate to the size of the Army They might expect that the inducements which had been offered would, in the course of the next few years, give them numbers even more satisfactory than those which had been forthcoming recently It would be impossible to keep up at all times an establishment of the Royal Army Medical Corps which would be adequate to a time when they were mobilising the whole of the Army for an expedition Ordinarily there were 107,000 regular troops in this country, but at this moment there were or there would be very soon, 208,000 in South Africa alone who looked to either the Royal Army Medical Corps or civilian medical men And besides there were now 100,000 regular troops in this country If the Royal Army Medical Corps were sufficient to deal with the present numbers it would have to be three times as large as would be necessary one year in 20, certainly one year in 10 Reference had been made to the great services of Sir William MacCormac and Mr Treves He was sorry that some gentlemen had insinuated that the services of the other five consulting surgeons had been too generously recognised A surgeon of the standing which these gentlemen had achieved who went out to South Africa did not only risk his life but he made a great financial sacrifice His income was to be told in thousands and to leave a *clientèle* of that size in order to proceed to South Africa with the possibility of not returning for five, six, or seven months was really, *in addition to the* personal sacrifice, to make a present of £5000 or £6000, or perhaps £10 000 to the taxpayers of the country And, therefore he did not think that £5000 a year was a shilling too much to pay for the services that such gentlemen had rendered They were asked to offer such inducements to the Royal Army Medical Corps as would enable them to obtain the heads of the medical profession They hoped that gradually in respect to the Army Medical Corps as in respect to every other branch of the service they would be able to improve the conditions under which men served, and that, therefore, they would obtain the best material within their reach The statement that a number of men were landed in South Africa who were at once invalided was one which deserved and would receive examination He understood it referred exclusively to reservists and militia men But let it not go abroad that there had been any great amount of sickness in South Africa The percentage of sickness in this expedition had been far lower than in any case of which there was record. It might be that some civilian practitioners had not their eyes trained to the fact of certain chronic complaints which were injurious to the soldier, but he thought he had proved that when they were sending away a force of the size of that now in South Africa they must bring to their aid a great amount of civilian assistance and it might be that the special attention usually paid had not been paid to those chronic complaints with which military officers were now acquainted in their bearing upon soldiers It was quite true that enteric fever had been prevalent in Ladysmith as it was usually where men were encamped for a lengthy period But the Royal Army Medical Corps had made enormous progress in sanitary appliances during recent years. Great attention had been bestowed upon the conditions which enabled them to fight with this disease and taking it all round, he believed the amount of enteric fever in this campaign had been very much lower, for instance than it was in the Soudan That *he attributed partly to the* climate of South Africa and also largely to the progress made in the sanitation of camps. As to inoculation the first experiments did not cover any great number of men and he thought the committee would agree with him that they had done what was pr for the experience of the campaign generally befo statistics The hon and gallant member for the (Colonel Blundell) had invited them to return to the regiment having its own medical man He was afraid he co out any hope that even in the modified degree the hon a gentleman advocated the system could be adopted

Sir WALTER FOSTER said he agreed with every word the Secretary had said about the work of the Royal Army Medical and about the aid given by the distinguished civil surgeons wh gone to South Africa When, however, one of these distinguished surgeons had to take an assistant with him he thought it was unnecessary generosity on the part of the War Office to pay the assistant at the same rate as his chief, indeed, he considered it an abuse of the whole system That was the point he wished to put before the Committee He thought it was an unnecessary step to put all the surgeons on the same footing

Dr FARQUHARSON put forward the suggestion that officers of the Royal Army Medical Corps should have study leave granted to them

Mr WYNDHAM assured the hon Member that this matter was under consideration On the subject of inoculation Mr Wyndham said that the whole system was voluntary Every soldier proceeding to South Africa was given the opportunity if he wished of being inoculated and a very large number—nearly 60 per cent in some regiments—had availed themselves of it The time for drawing conclusions from the experiment would be when they had the whole results before them at the end of the campaign

MONDAY, MARCH 19TH

Hospitals and Local Rates

Sir CAMERON GULL asked the First Lord of the Treasury whether, having regard to the representations which had been made to Her Majesty's Government through the President of the Local Government Board, he could state if the Government would this session undertake legislation relieving hospitals in Great Britain from local rates —Mr BALFOUR replied As my hon friend is aware I have already expressed sympathy with the object which he has in view, but the question is one which is surrounded by a considerable amount of difficulty, and I think that probably the best plan would be to have a committee of this House to look into the subject.

TUESDAY, MARCH 20TH

Medical Appointment in Dublin.

Mr ARTHUR MOORE asked the Attorney General for Ireland whether it was intended to institute the office of medical referee to the Registrar-General's office in Dublin and what were to be the duties and emoluments of the appointment.—The ATTORNEY GENERAL (Mr Atkinson) replied It is proposed to appoint a medical man to the office of superintendent at present vacant in the Department of the Registrar General The salary attached to the post will be £350 rising by £15 annually to £500 The duties of the officer will be those generally of a superintendent, but particularly with regard to the preparation of vital statistics.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

ADAMS, J., M.B., C.M. Edin., has been re-appointed Medical Officer by the Runcorn Rural District Council.

ADAMS, J. D., M.D. St. And., M.R.C.S., has been re-appointed Medical Officer by the Langport Rural District Council.

ADENEY, E. L., M.D., M.R.C.S., has been appointed Physician to th
General Hospital, Tunbridge Wells.

ALDERSON, WILFRID E., M.D., M.S. Durh., has been appointe
Honorary Assistant Surgeon, Fleming Memorial Hospital f
Children, Newcastle-on-Tyne, vice R. F. Craggs.

ANDERSON, A. J., M.B., C.M. Edin., has been appointed Medical Offic
for the Ashford Sanitary District of the Staines Union, vice F. Tothill, resigned.

BAXTER, S. E., L.R.C.P. Lond., M.R.C.S., has been appointed Medi
Officer for the Wollaston Sanitary District of the Wellingborou
Union, vice J. W. Orr, deceased.

BERRY, FREDERICK CHARLES, B.A., M.D., B.Ch. Dub., has been appointed Medical Officer of Health for Burnham (Somerset).

BONE, B. M., M.B., C.M. Edin., has been re-appointed Medical O
of Health by the Towyn District Council.

BOYD, JOHN J., M.B., Ch.M. Glasg., D.P.H. Cantab., has been appoi
Assistant Medical Officer of Health for the Borough and Po
Southampton.

BREWER, D., L.R.C.P. Lond., M.R.C.S., has been appointed S
Assistant Medical Officer for the Workhouse and Infirmary
Parish of St. Mary Abbots, Kensington.

BROOK, W. H. B., M.D. Lond., F.R.C.S. Eng., has been appointed C
for the Lincoln North District.

BRUZAUD, ALFRED S., M.R.C.S., L.R.C.P. Lond., has been appo
Senior Assistant House Surgeon to the Huddersfield Infirmary.

BUCKLEY, JOHN, L.S.A., has been appointed Medical Officer for the Hasland Sanitary District of the Chesterfield Union, vice R. Hamilton, resigned.

Ahill, M., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Whitby Sanitary District of the Wirral Union, vice H. A. Bredin, deceased.

Cameron, H. C., M.D. Glasg., has been appointed to the Chair of Clinical Surgery in the University of Glasgow.

Chapelle, R. L., M.R.C.S., L.R.C.P., L.S.A., has been appointed Medical Officer for the Stairfoot District by the Barnsley Board of Guardians.

Clowes, Ernest Francis, L.R.C.P. Lond., M.R.C.S., has been appointed Deputy Medical Officer for the Charfield District of the Thornbury Union.

Cooper, C. E., M.B., B.C. Cantab., has been appointed Medical Officer of Health for the Ivybridge Urban District, vice J. M. Randle, resigned.

Eddowes, Alfred, M.D. Edin., M.R.C.P. Lond., has been appointed Physician for Diseases of the Skin to St. George's and St. James's Dispensary, King-street, Regent-street, London.

Edington, George H., M.D., M.R.C.S., has been appointed Visiting Surgeon to the Glasgow Training Home for Nurses.

Forbes, Norman Hay, F.R.C.S. Edin., L.R.C.P. Lond., J.P., has been appointed Medical Officer for the South Eastern District of the National Fire Brigades Union.

Goldie, W. H., M.D., C.M. Edin., has been appointed Registrar to the Chelsea Hospital for Women, Fulham-road, London, S.W.

Halliell, A., M.B., F.R.C.S., has been appointed Ophthalmic Surgeon to the Hastings, St. Leonards, and East Sussex Hospital.

Hamilton, David Livingstone, L.R.C.P., F.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Timsbury District by the Clutton Board of Guardians, vice Mr. Wood, resigned.

Harcourt, J. C., L.R.C.P. Lond., M.R.C.S., has been appointed Assistant Medical Superintendent for the Infirmary of the City of London Union.

Hildyard, F. L., M.R.C.S., has been re-appointed Medical Officer by the Langport Rural District Council.

Hitchins, Charles Vernon, M.R.C.S., L.S.A., has been re-appointed Medical Officer of Health for the Weston-super-Mare Urban District.

Hudson, F., M.R.C.S., L.R.C.P. Lond., has been appointed Clinical Assistant to the Chelsea Hospital for Women, Fulham-road, London, S.W.

Jones, Richard, M.D. Edin., D.P.H. Cantab., has been re-appointed Medical Officer of Health by the Blaenau Festiniog Council.

Keer, J. C., M.R.C.S., has been re-appointed Medical Officer by the Plomesgate Rural District Council.

Legg, T. Percy, M.B. Lond., F.R.C.S. Eng., has been appointed Senior Surgical Registrar and Surgical Tutor, King's College Hospital, London.

MacNalty, F. C., M.A., M.D., M.Ch., T.C.D., has been appointed Surgeon to the City of Winchester Police, vice T. D. Richards, resigned.

Manknell, A., M.B. Lond., L.R.C.P., M.R.C.S., has been appointed Medical Officer for the First (East Bradford) Sanitary District of the Bradford (Yorks) Union, vice H. W. White, resigned.

Mason, William, L.R.C.P. & S. Edin., L.A.H. Dub., has been appointed Medical Officer of Health for St. Austell (Cornwall).

Mudge, Zachary Billing, M.R.C.S., L.R.C.P. Lond., has been re-appointed Medical Officer of Health for the Phillack (Cornwall) Urban District Council.

Mundey, Charles, M.R.C.S., has been re-appointed Medical Officer by the Langport Rural District Council.

Mussen, A. A., M.D., D.P.H., has been appointed Assistant Medical Officer of Health for the City of Liverpool, vice E. P. Manby, resigned.

Nettle, William, M.R.C.S., L.S.A. Lond., has been re-appointed Medical Officer of Health for Liskeard.

Nobbs, A., M.D., C.M. Edin., has been appointed Clinical Assistant to the Chelsea Hospital for Women, Fulham-road, London, S.W.

Nott, H. W., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Eastham Sanitary District of the Wirral Union, vice H. A. Bredin, deceased.

Pardington, G. L., M.D. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Physician to the General Hospital, Tunbridge Wells.

Rix, B., M.R.C.S., L.S.A., has been appointed Surgeon to the General Hospital, Tunbridge Wells.

Simmons, Benjamin, M.R.C.S., L.S.A., has been re-appointed Medical Officer for three years for the Charfield District of the Thornbury Union.

Spencer, F. M., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Medical Officer for the Ninth Sanitary District of the Totnes Union, vice T. Lakeman, deceased.

Stevens, Bertram Crossfield, M.B., B.S. Durh., M.R.C.S., L.R.C.P., L.S.A., has been appointed Senior House Surgeon to the Huddersfield Infirmary.

Tarbet, P. R., L.R.C.P. Lond., M.R.C.S., has been appointed Senior Assistant Medical Officer for the Infirmary of the Parish of St. Pancras, vice T. S. Boden, resigned.

Taylor, J., M.D. Aberd., has been appointed Medical Officer to the General Post Office, Leith.

The Chief Inspector of Factories announces the following appointments of Certifying Surgeons under the Factory Acts:—Bernard Robinson, L.R.C.P. Lond., M.R.C.S., for the Civil Parishes of Croxden and Rocester in the Uttoxeter Rural District; J. M. Johnson, M.D., M.R.C.S., for Leek Urban District, Leek Rural District except the Civil Parishes of Norton in the Moors and the Civil Parishes of Cheddleton and Consall in Cheadle Rural District; L. I. M. Neave, M.B., Ch.B. Edin., for the Civil Parishes of Guthrie, Kirkden, Rescobie (south of the Caledonian Railway Line), Dunnichen (east of the road running through Dunnichen and Bowriefauld) and Kinnell in the county of Forfar; and R. B. Mahon, M.D. Irel., F.R.C.S. Eng., for the Ballinrobe Dispensary District, County Mayo.

Thomas, A. H., M.B., Ch.B. Edin., has been appointed Medical Officer for the Aldborough Sanitary District of the Great Ouseburn Union, vice J. Sedgwick, resigned.

Thomson, H. Campbell, M.D., M.R.C.P. Lond., has been appointed Assistant Physician to the Middlesex Hospital.

Valentine, W., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer for the Fourth Sanitary District of the Warrington Union, vice J. W. Watkins, resigned.

Yearsley, Macleod, F.R.C.S., has been appointed Surgeon to the Royal Ear Hospital, Soho-square, London.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Birmingham General Dispensary.—Vacancy on the staff of Resident Surgeon, unmarried. Salary £150 per annum. £30 a year allowed for cab hire, and furnished rooms, fire, lights, and attendance.

Bootle Borough Hospital, Liverpool.—Junior Resident Medical Officer. Salary £50, with board, lodging, and washing.

Borough of Crewe.—Medical Officer of Health. Commencing salary £300 per annum. Applications to the Town Clerk, Municipal Offices, Crewe.

Canning Town Medical Mission Dispensary, 520, Barking-road, London.—Assistant Medical Officer (qualified woman). Board and lodging provided.

Cardiff Infirmary.—Assistant House Physician for six months. Salary at the rate of £50 per annum, with board, washing and apartments. Also Resident Medical Officer for three years. Salary £100 per annum, with board, washing, and furnished apartments.

Chelsea Hospital for Women, Fulham-road, S.W.—Clinical Assistant. Tenable for three months on payment of 3 guineas.

Clayton Hospital and Wakefield General Dispensary, Wakefield.—Junior House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

Cumberland and Westmorland Asylum, Garlands, Carlisle.—Junior Assistant Medical Officer, unmarried. Salary £100 a year, with board and residence.

East Sussex County Council.—Consulting Medical Officer for one year. Honorarium 100 guineas and travelling expenses.

Glasgow District Asylum and Mental Hospital, Gartloch.—Medical Officer (Junior Assistant or Locum Tenens). Remuneration as may be arranged. Apply to the Clerk, Glasgow District Lunacy Board, 38, Cochrane-street, Glasgow.

Govan District Asylum, Crookston, near Paisley, N.B.—Junior Assistant Medical Officer. Salary £120 a year, with rooms, board, laundry, and attendance.

Harris Parish Council, for the Southern Division of Harris.—Medical Officer. Salary £80. Apply to Mr. Thomas Wilson, Solicitor, Lochmaddy, Clerk.

Hospital for Consumption and Diseases of the Chest, Brompton.—Resident House Physicians for six months. Honorarium £25.

Hospital for Sick Children, Great Ormond-street, Bloomsbury, London.—House Physician for six months, unmarried. Salary £20, with board and residence in the hospital.

Hull Royal Infirmary.—Honorary Assistant Surgeon for five years.

Hulme Dispensary, Dale-street, Stretford-road, Manchester.—House Surgeon. Salary £150 per annum, with apartments, attendance, coal, and gas.

Italian Hospital, Queen-square, London, W.C.—House Surgeon. Salary £50 per annum, with board, residence, and laundry.

Leeds Public Dispensary.—Junior Resident Medical Officer. Salary £85 per annum.

Lincoln Hospital for the Insane.—Assistant Medical Officer. Salary £100.

Liverpool Infirmary for Children, Myrtle-street.—House Surgeon. Salary £25 per annum, with board and lodging. Also Assistant House Surgeon for six months. Salary £25 for that period, with board and lodging.

Liverpool Stanley Hospital.—Senior House Surgeon. Salary £80, with board, residence, and washing.

London County Asylum, Horton.—Medical Superintendent, Horton Asylum, Epsom, now in course of erection. Salary £1000 per annum, with unfurnished house, rates, taxes and water supply free. Applications to the Clerk of the Asylums Committee, Office, 6, Waterloo-place, London, S.W.

Metropolitan Asylums Board.—Four Assistant Medical Officers at the Fever and Small-pox Hospitals, unmarried. Salary £160 per annum the first year, and conditionally £180 the second, and £200 the third and subsequent years, with board, lodging, attendance, and washing, subject to statutory deductions. Applications to the Offices of the Board, corner of Carmelite-street, Embankment, E.C.

New Zealand Public Lunatic Asylums.—Two Assistant Medical Officers, unmarried. Salary £250, with board, lodging, and washing. Apply to the Agent General for New Zealand, 13, Victoria-street, London, S.W.

North Riding Infirmary, Middlesborough-on-Tees.—Assistant House Surgeon. Salary £75 a year, with lodging, board, and washing. No beer allowed.

Paddington Green Children's Hospital, London.—House Physician and House Surgeon for six months. Salary at the rate of 50 guineas a year, with board and residence.

Paddington Infirmary.—Resident Clinical Assistant and Second Assistant to the Medical Superintendent for six months. Board, residence, and washing provided, and an honorarium at the rate of £50 per annum conditionally. Personal application to Dr. M. F. Squire at the Infirmary, [illegible] Harrow-road, W.

Parish of Rousay and Egilsay, Orkney.—Resident Medical Officer (male or female). Salary £51 sterling per annum. Apply to the Clerk of Parish Council, Rousay, Orkney.

Peckham House Asylum, Peckham.—Junior Assistant Medical Officer. Salary £120 per annum, with board and lodging.

Licences of the conjoint licensing bodies in England, Ireland, and Scotland at the present time are far more searching and superior than any of the universities in the United Kingdom and the percentage of rejections is very much higher. My statement can be verified by a reference to the Minutes of the General Medical Council. The members of the General Medical Council occasionally visit the different examinations.

The following extracts may be of interest to the Admiralty. The visitors report on one university: "Our joint opinion is 'that the examination for the Degree of Bachelor of Medicine in the University of —— is inadequate for a degree admitting to the Medical Register and that the candidates were not sufficiently tested," &c. (see Minutes, General Medical Council, vol. xxiii., p. 344). The visitors report on another university: "We were much impressed with the insufficient knowledge of the essential subjects of the M.B. examination and the imperfect clinical training which a large portion of the candidates displayed" (see Minutes, General Medical Council, vol xxiii., p. 392)

I am, Sirs, yours faithfully,

March 14th, 1900. JUSTICE.

CAVE.

THE *Teignmouth Post* of March 9th has the following advertisement.—

> LADY MANAGER, or Lady and Gentleman, REQUIRED for Branch Office about to be opened by The British Viave Co. (Ld). Small investment necessary, but returnable at end of first year if contract cancelled by either party.—Address, FRANK RIDDING, Manager, British Viave Co, Ebrington House, Plymouth.

If the British Viave Co. is the same as the British Vlavi Co. we advise ladies and gentlemen and everyone else to leave the institution severely alone. See THE LANCET, March 10th, 1900, page 742.

THE LOT OF THE PUBLIC VACCINATOR.

To the Editors of THE LANCET.

SIRS,—In the capacity of a public vaccinator I visited yesterday the home of a child six months old whose name appeared on my list. The day previous (March 12th) I had visited the house where the child was born—a distance of about eight miles from my surgery—but found that the parents had moved to the house I visited yesterday. When I arrived there the mother was out and had left the child in charge of her sister. There was also a neighbour in the house at the time I informed them of the object of my visit and they saw no reason why I should wait until the mother's return, which was indefinite. I vaccinated the child accordingly, and after applying the necessary antiseptic pad the mother came in and began "blowing me up" and said that I had no legal right to do what I did. I took trouble to explain to her the circumstances, but to no purpose; she was adamant, and I left the house under heavy artillery fire. Kindly let me know your view of the case. I ought to say that she could not class herself a "conscientious objector."

I am, Sirs, yours faithfully,

March 14th, 1900 A PUBLIC VACCINATOR.

*** Our correspondent must obtain legal advice.—ED. L.

THE HYPODERMIC INJECTION OF ARSENIC.

C. H. would be grateful for information as to previous experiences, references to literature, and risks run as to hypodermic injections of arsenic, having regard to a case of severe leukæmia at present under his care. Into this patient have been injected hypodermically 5·33 grains of arsenious acid during 11 weeks inclusive of 14 days' interval, and 39½ grains (*sic*) of arseniate of soda during eight weeks inclusive of one week's interval, the whole course extending over 20 weeks. There are no signs of poisoning up to the present date, over a month since cessation of the treatment, and concurrent improvement of the blood during the injections.

"POPULAR MEDICINE."

To the Editors of THE LANCET.

SIRS,—Referring to your remarks in THE LANCET of March 10th on *Leach's Family Dressmaker* permit me to say that it is a perfectly erroneous statement that medical queries are either invited or answered in that journal; but were this the case we should but be adopting the methods of many other journals of a much higher class. The reply you quoted concerned the matter of a woman's personal appearance and not her health, and invidious as it may be to "apply to a popular paper" for advice it is well known that this is the only resource, as *doctors are apt to "pooh pooh" or smile good-naturedly over any such* query. It appears to me monstrously unfair that you should single out an odd bit of advice from such a paper as our own and use it in the connexion that it was used in, while others who sin far more and who *do* give real medical advice should be unnoticed. I have nothing to do with the management of the advertisements and fully endorse what you say respecting them; but were there no other dressmaking journals to which you could have drawn attention?

I am, Sirs, yours faithfully,

M. CHRISTINE, Toilet Editress.

PS.—You must at least adjudge me honest, since I gave a simple remedy *before* suggesting the "half crown bottle."

*** The statement which M. Christine calls "perfectly erroneous" was not made by us. The fact that other papers offend in a similar manner does not exonerate *Leach's Family Dressmaker* in respect of the matters to which we have called attention. If advertisements of abortifacient mixtures continue to be inserted in her paper it is *open for* Toilet Editress *to resign her position. During a recent trial* at Birmingham Mr. Justice Darling repeated his intention of sending to gaol, when opportunity served him, persons connected with the dissemination of these advertisements.—ED. L.

WHO IS RESPONSIBLE?

To the Editors of THE LANCET.

SIRS,—I should be glad to hear your opinion at your earliest convenience on the following point: A dentist (A) asks a medical practitioner (B) to come and give gas to a lady (C) who is having some teeth removed in order to have a new set. B is until this period *quite unacquainted with C who is A's patient.* As there are over a dozen stumps for removal B attends at A's house and gives gas on seven separate days. Nothing is said as to B's fee. A few weeks after B writes inquiring about the same. As no reply is received B writes a second letter to which also there is no reply. Two months have since elapsed and B has still heard nothing from A, who is still to his knowledge in the town. Who is really responsible for B's fees, the dentist or the patient? *A is an L D.S.*

I am, Sirs, your faithfully,

March 19th, 1900. M.R.C.S.

*** In our view A is responsible for the fees, and he is certainly wanting in courtesy in sending no reply to B's letters. Is B certain that A received them? B must, of course, consult a solicitor before taking legal proceedings.—ED. L.

A STORY OF GEOGRAPHY.

THE *Daily Chronicle* publishes a good little story illustrating the bias that exists in the British mind towards the foreign spa and incidentally showing that a certain wealthy clubman is a poor geographer. The story is as follows:—

> "A certain wealthy clubman was recently advised to try a course of baths at Droitwich. He had heard vaguely of the place and associating all forms of water-cure with the continent imagined that a town so named must be somewhere in Hungary or Poland. Having been in the habit of taking Paris as the base of operations in all his continental trips he took a ticket hither, put up at the Hôtel Bristol, and told the omniscient hotel clerk to work out the route to Droitwich. The clerk searched all the continental time-tables and guides to continental mineral cures in vain and had to admit that for once he was beaten. The Englishman, greatly annoyed, took a cab to Cook's Paris office, where he was informed that the route to Droitwich lay through London, whence it could be reached in about three hours."

ŒDEMA OF THE LOWER EXTREMITIES FOLLOWING INFLUENZA.

To the Editors of THE LANCET.

SIRS,—Can any of your readers inform me what is the best treatment for the dropsical swelling of the lower extremities which occasionally takes place after influenza? I am, Sirs, yours faithfully,

March 19th, 1900. M.D., &c.

AN ASPIRANT TO QUACKERY.

WE *have received the following naive letter addressed to the* "Editorial Dept.":—

> DEAR SIR,—Do i require a License for making ointment to sell, and for making embrocation for sale, "ringworm," Cure, "Corn Cure" "Cure for cuts" Lct., or could i make and sell 'corn cure' only without the above, i think it would not be "patent. Medicine." any pacticlars on above will oblige. Yours
>
> E. M.

We suppress E. M.'s address and full name, for we believe him to be only an unconscious offender, and are not certain that in writing to us he has desired publicity. The handwriting is in keeping with the literary style. Is it not extraordinary that a man not only without special training but without the ordinary rudiments of education should feel himself quite capable of treating the minor maladies of the public medically? E. M. would, we are certain, not dream of attempting to clean a watch without understanding its mechanism.

PRINCIPLES WHICH OUGHT TO CONTROL THE CONSTRUCTION OF MODERN ASYLUMS

DR. R. H. STEEN of the West Sussex County Asylum publishes a paper briefly dealing with the above in the *Journal of Mental Science* (January, 1900). After a short historical review of the evolution of asylum architecture an account is given of modern asylum plans such as are embodied in the "pavilion" systems in vogue at the present day. This plan is to build the several blocks apart from one another and to make them each in a measure self-contained—i.e., each with its own dormitory, day room, dining-room, bathroom, lavatories, store-rooms, &c. These blocks are connected by corridors and may be arranged in linear series or in H-shape, or on the echelon plan and its modifications. Examples and plans are given to elucidate the descriptions of existing asylums. The detached villa system—viz., small home like buildings spread over a large estate—is illustrated by an account and plan of the celebrated Alt-Scherbitz Asylum near

Leipzig, built for 960 patients on an estate of 750 acres and which has become the prototype of other and similar institutions in Europe and America. Modern treatment demands that a hospital block furnished with the means and appliances for the most advanced medical and surgical procedure should be added to all large asylums. The best position for this is in the central block between the male and female sides, and the first floor should contain isolation rooms, sick attendants' room, and a small dormitory. The division of an asylum into two portions, acute and chronic, is, according to Dr. Steen, open to objection.

THE WOMB QUACK.

IN the *Lincolnshire Echo* of March 2nd appears an advertisement setting forth the talents of a certain Mrs. Slater. The advertisement is embellished with a portrait of a woman who, we take it, is the Mrs. Slater in question. We learn from the advertisement that she will attend Lincoln on March 3rd to afford an opportunity for ladies to consult her. "Her skill on all womb and internal complaints is well known throughout England. Every sufferer wearing an inward instrument ought to consult her. The most eminent operating surgeon alive said: 'If the use of inward instruments were persisted in they would have to build a hospital to treat the cancers and tumours created by them.'" We further learn that the Compress Belt for stout ladies is a great boon—first, it reduces measurement, and, secondly, it renders breathing easier. Further, it is worn by doctors' wives; it is worn by clergymen's wives; it is worn by hotel-keepers. We do not quite see that this proves the article to be so excellent for the same might be said of many other articles—e g., boots. Mrs. Slater also gives special and careful attention to all spinal complaints. Special bandages are to be obtained for varicose veins and swellings in the legs and Mr. Slater attends for men. All advice is free. We suppose the advice given is to buy a belt, for we do not for one moment imagine that Mr. and Mrs. Slater are actuated by pure benevolence. The advertising "womb doctor" is always a pestilent person and does an incalculable amount of harm.

TO MEDICAL FREEMASONS.

To the Editors of THE LANCET.

SIRS,—Will you permit me through your columns to bring before the notice of medical Freemasons the cases of Herbert Eric Skrimshire and Gwendoline Hudson, No. 36 and No. 26 respectively on the lists of candidates for election to the Boys' and Girls' Schools in April?

I am, Sirs, yours faithfully,

Woking, March 20th, 1900. T. CAWLEY EAGER.

*** "A Medical Mason" also writes to ask for support for these candidates who are, he states, the only children of medical Freemasons seeking election to the Masonic Schools on the present occasion.—ED. L.

LUNACY CERTIFICATES AND MEDICAL JUSTICES OF THE PEACE.

To the Editors of THE LANCET.

SIRS,—I shall be glad to have the opinion of your readers as to the action of C in the subjoined and like instances. A, B, C, and D are four practitioners in the same district and ostensibly the best of friends. C is also a Justice of the Peace. A is asked to visit an old patient who has become insane and, understanding that the friends desire the patient to go into a county asylum at a small weekly fee, he calls in B to examine and certify. A and B both issue certificates and an order for removal is signed by C. It is subsequently found that there is no county asylum in the county which takes in a paying patient. Accordingly, the relieving officer is called in who instructs C to judicially visit the patient who, in his turn, requests D to examine the case. C appears to have some special predilection for D and in all lunacy cases occurring in the district invariably seems to send D to examine, perfectly regardless of the professional attendant under whose charge the patient has been (on one occasion for 12 years in A's experience). 1. C may be within his legal rights, but is his action professionally friendly to either A or B and is it not likely to damage the prestige of both? 2. Is A correct in the feeling that the Commissioners of Lunacy prefer that certificates of lunacy should be issued (where only one is required) by the medical attendant who has had previous charge of the case and is therefore in a better position than any stranger to judge its merits?

I am, Sirs, yours faithfully,

March 20th, 1900. TWENTY YEARS' PRACTICE.

*** We can quite understand that A in the circumstances mentioned should feel a little disappointed at not being called in to certify in the case of his own patient, but there are several possible explanations of the course adopted by C. In the first place it is very usual for certain justices invariably, and as a matter of routine, to employ a certain medical man who knows the ordinary procedure for parish cases, that is to say, those which are removed to the county asylum. Although the guardians have no legal right to do so they sometimes stipulate for the employment of a certain medical man, and such stipulation has considerable moral, though no legal, binding on the justices. In point of fact, a contract not infrequently exists between the guardians and a certain medical man for the certification of such cases. Again, it is quite possible that C, although having the greatest respect for the opinions of A and B, might have wished for yet another and independent opinion on the state of the patient. In view, therefore, of all the circumstances of the case we cannot regard the action of C as being unfriendly either professionally or in any other respect, nor is it, in our opinion, likely to damage the prestige of either A or B. In answer to the second question the Commissioners of Lunacy have expressed no opinion upon the point and they invariably leave such matters entirely (as they must do in point of law) to the justice concerned in the case. It is he alone who is responsible for the legal procedure.—ED. L.

F. J. A. B.—We recommend the following list of books:—(1) "Hygiene and Public Health," Whitelegge (Cassell and Co., London); (2) Knight's "Annotated Model By-laws" (Knight and Co., London); (3) "Vital Statistics," Newsholme (Sonnenschein and Co., London); (4) "Manual of Bacteriology," Muir and Ritchie (Pentland, London and Edinburgh), (5) "Public Health Laboratory Work," Kenwood (Lewis, London). The above are essential; the following may also be consulted:—"Water Supplies," Thresh (Rebman Publishing Company, London); "Micro-organisms in Water," Frankland (Longmans and Co., London); the chapter on Water Analysis in "Volumetric Analysis," Sutton (Churchill, London); "Purification of Sewage," Barwise (Crosby, Lockwood, and Co., London); "Law and Chemistry of Food and Drugs," Robinson and Cribb (Rebman Publishing Company); "Cattle Tuberculosis," Legge and Sessions (Baillière, Tindall, and Cox, London). We cannot decide which is the more difficult examination.

A Sufferer should consult his medical adviser. The condition is dependent upon many different causes. If it persists after treatment his medical adviser will probably suggest that he should see some other medical man in consultation. We cannot insert the letter.

Maque.—The question of midwifery nurses being of either sex has been raised before, but our correspondent may help the class to which he alludes by continuing to ask it. The address he inquires for is 12, Buckingham-street, Strand, London, W.C.

U.L.M.S.—We lay down no geographical limits, but the Fund is designed to meet emergencies.

L.S.A.—1. Yes. 2. About 14 years ago.

ERRATUM.—In the annotation in THE LANCET of March 17th, p. 787, upon the National Association for the Prevention of Consumption, the name of the seconder of the report was erroneously printed as Dr. L. H. Bryson. It should have been Dr. W. B. Ransom (Nottingham).

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

FRIDAY (30th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M., Ophthalmic 10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (2 P.M. and 6 P.M.).

SATURDAY (31st).—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), London Throat (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (26th).—Medical Society of London.—8.30 P.M. Dr. Luff: The Gelatinous Form of Sodium Biurate and its bearing on the Treatment of Gout.—Dr. Bain The Action of Various Drugs and Diets on the Excretion of Nitrogen in Gout.

TUESDAY (27th).—Childhood Society (Library of the Sanitary Institute, 72, Margaret-street, W.)—8 P.M. Mr. S. H. Wells: Science Teaching.

Royal Medical and Chirurgical Society (20, Hanover-square, W.).—Dr. Bowles and Mr. G. R. Turner: A Case of Rupture of the Œsophagus caused by Vomiting.—Mr. A. Pearce Gould: A Case of Sarcomatous Tumour of the Gastro-Hepatic Omentum removed by Operation, with Remarks on the Diagnosis of such Tumours.

WEDNESDAY (28th).—Dermatological Society of Great Britain and Ireland (20, Hanover-square, W.)—4.30 P.M. Informal Exhibition of Cases. 5 P.M. Ordinary Meeting.

Hunterian Society (London Institution, Finsbury circus).—8.30 P.M. The President: Address. Paper:—Dr. D. Ross: Some Points in the Therapeutics of Gout.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (26th).—Medical Graduates' College and Polyclinic (22, Chenies street, W.C.).—4 P.M. Dr. A. Whitfield: Consultation. (Skin.)

TUESDAY (27th).—Royal College of Physicians of London.—5 P.M. Dr. P. Horton Smith: The Typhoid Bacillus and Typhoid Fever. (Goulstonian Lecture.)

Royal Institution of Great Britain.—3 P.M. Prof. E. Ray Lankester: The Structure and Classification of Fishes.

Medical Graduates' College and Polyclinic (22, Chenies street, W.C.).—4 P.M. Dr. W. Miller Ord Consultation. (Medical.)

WEDNESDAY (28th).—Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—5 P.M. Mr. J. Hutchinson: Clinical Lecture.—The Present-day Treatment of Syphilis. 6 P.M. Annual Meeting

Hospital for Consumption and Diseases of the Chest (Brompton).—4 P.M. Dr Acland: Cases illustrating various Types of Pulmonary Tuberculosis

The Hospital for Sick Children (Gt. Ormond-street, W.C.).—4 P.M. Mr. Pitts: *Demonstration of Selected Cases.*

THURSDAY (29th).—Royal College of Physicians of London.—5 P.M. Dr. W. B. Cheadle. Some Cirrhoses of the Liver. (Lumleian Lecture.)

Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.).—4 P.M. Mr. J. Hutchinson: Consultation. (Surgical.)

FRIDAY (30th).—Medical Graduates' College and Polyclinic (22, Chenies-street, W.C.)—4 P.M. Mr. T. Collins: Consultation. (Eye, Ear, Nose and Throat.) 5-7 P.M. Mr. J. Griffith: Class. Practical Ophthalmology. Demonstration IV.

Royal Institution of Great Britain.—9 P.M. Prof. J. A. Thomson: Facts of Inheritance.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of The Lancet should be addressed *exclusively* "To the Editors," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE, OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of The Lancet *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index to Vol II. of 1899, which was completed with the issue of Dec 30th, and the Title-page to the Volume, were given in The Lancet of Jan. 6th.

VOLUMES AND CASES.

Volumes for the second half of the year 1899 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half-year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of The Lancet at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach The Lancet Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to The Lancet Offices.

Subscribers, by sending their subscriptions direct to The Lancet Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from The Lancet Offices or from Agents, are:—

For the United Kingdom		To the Colonies and Abroad.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance.

Subscribers abroad are particularly requested to note the rates of subscriptions given above. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of The Lancet necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of The Lancet have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—The Manager, The Lancet Offices, 423, Strand, London, England.

Communications, Letters, &c., have been received from—

A.—Ashwood House, Kingswinford, Medical Superintendent of; Messrs. Allen and Hanburys, Lond.; Messrs. Ayrton and Saunders, Liverpool; Anglo-Swiss Condensed Milk Co., Lond.

B.—Mr. C. A. G. Browne, Lond.; B. M. B.; T. B. Browne, Ltd., Lond.; Mr. A. Benthall, Lond.; Brin's Oxygen Co., Lond.; Mr. H. Browne, Lond.; Mr. Lennox Browne, Lond.; Mr. H. Borland, Glasgow; Mr E. C. Brodrick, Tavistock; Dr. V. Burrow, Tring; Mr. H. Brown, Leeds; Mr. L. A. Bidwell, Lond.; Bucklow Rural District, Medical Officer of Health of; Borough of Crewe, Medical Officer of Health of; Dr. Burton-Fanning, Norwich; Dr. H. M. W. Bridgman, San Remo.

C.—Dr. Alfred Cox, Gateshead; Childhood Society, Lond., Secretary of; Professor Corfield, Lond.; Chamfbandratintz; Benagaria; Cornwall County Council, Clerk of; Dr. A. Cordes, Geneva; Messrs. Cassell and Co., Lond.; Canning Town Medical Mission, Resident Medical Officer of; Mrs. Chapman, Lond.; Carnos, Ltd., Great Grimsby; Mrs. Cullen, Cheltenham; Clayton Hospital, Wakefield, Hon. Secretary of; Chelsea Hospital for Women, Secretary of; Dr. F. G. Clemow, Lond.

D.—Dr. D Duncan, Chester-le-Street; Sir Dyce Duckworth, Lond.; Dr. C. R. Drysdale, Lond.; Dr. S. Delépine, Manchester; Mr. A. Duke, Cheltenham; Dental Hospital of London, Secretary of; Deutscher Inserenten-Verband, Cologne.

E.—Mr. T. C. Eager, Woking; East End Mothers' Home, Secretary of.

F.—F. C. H. M.; F. J. McA.

G.—Mr. A. R. Galloway, Aberdeen; Mr. T. M. Griffiths, St. Louis, U.S A.; Messrs. Gallatly and Ferry, Lond.; Messrs. R W. Greeff and Co., Lond.; Gledhill's Medical Agency, Lond.

H.—Dr. de Haviland Hall, Lond.; Dr. E. M. Hasbrouck, Washington; Mr. David Harris, Lond.; Mr. T. E. Hayward, Haydock; Mr. Hayward-Pinch, Lond.; Dr. J. Hunter, Linlithgow; Messrs. J. Haddon and Co., Lond.; Hulme Dispensary, Manchester; Hart Accumulator Co., Lond; Dr. N. C. Hatherley, South Molton; Dr. Horton-Smith, Lond.; Hull Royal Infirmary, Secretary of; Hendon Grove, Hendon, Medical Superintendent of; Mr. J. J. Harding, Ballincollig.

I.—Mr. S. Iles, Bristol; Mr. E. H. Ireland, Lond.

J.—Mr. G. H. Johnston, Ticehurst; Jeyes' Sanitary Compounds Co., Lond.; J. H.; Dr. H. Joseph, Berlin; Dr. W. W. Jones, Bath; Mr. R. Johnson, Hollesley Bay; J. Y. Y.

K.—Dr. W. Kirk, Ichang, China; Mr. B. Kuhn, Lond.; Dr. J. P. Kitson, Cleobury Mortimer; Mr. W. Kühlenthal, Lond.; Mrs. Keene, Cambridge; Professor Stanley Kent, Bristol.

L.—Liverpool School of Tropical Diseases, Secretary of; Liverpool Infirmary for Children, Secretary of; Liverpool Stanley Hospital, Hon. Secretary of; Mrs. Lake, Guildford; Mr. R. M. Littler, *Southport*; *London and Counties* Medical Protection Society, Hon. Secretary of; Leeds Public Dispensary, Secretary of.

M.—Dr. F. A. H. Michôd, Lond.; Dr. W. G. Mortimer, Thorne; Mutual Life Insurance Co., New York, General Manager of; Messrs. May and Rowden, Lond.; Meaby's Triticumina Co., Reading; Medical Society of Victoria, *Melbourne, Hon. Secretary of*; Messrs. C. Mitchell and Co., Lond.; Macclesfield Infirmary, Secretary of; Medical Graduates' College, Lond.; Messrs. Masson et Cie, Paris; Messrs. P. Macfadyen and Co., Lond.; Dr. W. Murrell, Lond.; Dr. H. C. Marr, Lenzie.

N.—N. C.

P.—Sir R. Douglas Powell, Lond.; Dr. C. E. Paget, Northampton; Mr. Y. J. Pentland, Edinburgh; Prudential Assurance Co, Lond.; Paddington Infirmary, Clerk of; Public Vaccinator; Mr. J. F. Pink, Lond.; Dr. R. Pearson, Lond.; Messrs. A. H. Poole and Co., Waterford; Price's Patent Candle Co, Lond.; Mr. T. Parr, Stafford; Dr. J. B. Pike.

R.—Dr. W. B. Ransom, Nottingham; Royal Institute of Painters in Water Colours, Secretary of; Messrs. Reynolds and Branson, Leeds; Dr. A. F. Rogers, Ottawa, Canada; Dr. J. Ramsay, Launceston, Tasmania; Royal College of Surgeons, Lond., Secretary of; Mr. W. Rees, Brynamman; Mr. E. W. Richmond, Lond.; Royal London Ophthalmic Hospital, Secretary of, Royal National Pension Fund for Nurses, Secretary of; Royal Aquarium, Lond., Manager of; Rochford Union, Southend-on-Sea, Clerk of; Royal Surrey County Hospital, Guildford, Assistant Secretary of; Ramsgate, &c, Royal Dispensary, Secretary of; Dr. A. H Robinson, Low Moor; Messrs. G. Reiss and Co., Manchester.

S.—Mr. Simeon Snell, Sheffield; Dr. Septimus Sunderland, Lond.; Mr. J. V. U. Somers, Richmond, Yorks; Mr. A. A. Stempel, Lond.; Dr. W. A. Salmond, Acton; St. *Mungo's College, Glasgow*, Secretary of; Sufferer, Liverpool; St. Margaret and St. John, Westminster, Medical Officer of Health of; Stockport Infirmary, Secretary of.

T.—Mr. J. V. Taylor, San Francisco; Messrs. Tillett and Yeoman, Lond.

V.—Miss Vincent, Lond.

W.—Mr. C. A Wright, Lond.; Dr. C. St.J. Wright, Felsted; Messrs. W. Wood and Co., Lond.; Mr. J. Wright, Ravenscraig; Mr. E. S. Warrilow, Lond.; Mr. L. W. Williams, Lond.; Wigan, *Medical Officer of Health of*; Westport, Medical Officer of Health of; Messrs. Wright, Dain, Peyton, and Co., Birmingham; Messrs. Ward, Lock, and Co. Lond.; *Worcester Herald*, Manager of.

Y.—Yorkshire College, Leeds, Clerk of.

Letters, each with enclosure, are also acknowledged from—

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France —J. ASTIER, 8, Rue Traversière, Asnières, Paris.

The Lumleian Lectures

ON

SOME CIRRHOSES OF THE LIVER.

Delivered before the Royal College of Physicians of London

BY W. B. CHEADLE, M.D. CANTAB., F.R.C.P. LOND.,

SENIOR PHYSICIAN AND LECTURER ON CLINICAL MEDICINE AT ST. MARY'S HOSPITAL; CONSULTING PHYSICIAN TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

LECTURE I.[1]

Delivered on March 29th.

MR. PRESIDENT AND GENTLEMEN,—When I was invited to give these lectures I felt very sensible of the honour conferred upon me. As soon, however, as the glamour of the situation moderated and the prospect cleared, I realised how difficult it would be worthily to fulfil the duty laid upon me. I called to mind the ox and the charger of the fable—"optat ephippia bos piger; optat arare caballus." There is always, however, something of value to be learned from the experience of the honest observer, and in this belief I venture to offer these results of my clinical experience.

In these later times that important organ, the liver, has, I think, hardly received the attention which it deserves. The rapid development of our knowledge of the nervous system and its diseases has largely absorbed the interest of clinical observers, and the apotheosis of the bacterium and *the bacillus has caused those organs which do not favour* their exploitation to be somewhat neglected. The heart, indeed, has held its own. It has a natural attractiveness, even fascination, for the clinical observer. The mechanism is well understood; the condition of its machinery is ascertained with comparative ease and precision by various simple means. The lungs, also, in like manner are open to physical examination, and are, moreover, the favourite haunt of micro-organisms; they also retain their position of clinical interest, while the kidneys, although hidden away from easy physical examination, furnish a means of testing their condition through the secretion of urine and thus secure their hold upon medical investigation. That great composite gland, the liver, is, however, less readily dealt with. Not only are its functions more complex and varied than those of any other abdominal organ, but it is a still and silent worker, doing its office noiselessly and without movement. There is no portion of the digestive machinery whose integrity is more important to nutrition; none in which slight disturbances are more common, or more productive of discomfort and impaired health; and yet there is no one of the viscera whose aberrations of function are less accurately and scientifically ascertained

The physical condition of the liver can only be examined during life partially by the sense of touch, aided in minor degree by auscultation and percussion. The state of its complex functions can only be inferred—and that imperfectly—by the effects of their disorder upon other organs. The difficulties which beset the investigation of the condition of the liver and its functions during life have prevented full knowledge being gained on certain points in its pathology, and the clinical history of its diseases has remained in many respects unsettled. Much excellent work has been done by many physicians during the last 20 years—but much remains to be done. Amongst undetermined questions with regard to disorders of the liver—questions, which still remain the subject of discussion, and about which opinion is not yet finally formed—are some relating to the cirrhoses; and it will be my endeavour in these lectures to throw light upon certain of the obscurities which still beset this group of hepatic affections.

Since my attention has been specially directed to this subject of hepatic cirrhoses a series of cases have come under my observation which have not corresponded strictly or satisfactorily, in clinical or pathological characters, with the description of the disease in its different forms as set forth by authority. I belive that the views generally regarded as established require modification and expansion. The lines laid down are altogether too absolute and too rigid. The conclusions drawn at first and accepted almost without question are necessarily built upon imperfect knowledge and require revision from time to time as experience grows. The clinical picture of cirrhosis, for example, gloomy as is the reality in many respects, has been painted in more melancholy colours than is altogether warranted by facts. The interest in the disease has centred in the post-mortem room rather than at the bedside; and the revelations of the former have overshadowed the brighter possibilities which are sometimes indicated by the latter. In passing judgment upon the disease all forms of it have commonly been vaguely run together under the general term "cirrhosis"; and the last stage of the most fatal condition has been regarded as representative; the remediable and the irremediable have been confused together in one stereotyped picture of unalterable disease, and this absolutely unfavourable verdict has, I think, been largely influenced by the disastrous results of mistaken treatment.

Cirrhosis of the liver occurs in various forms and in different degrees It does not, as some would appear to conceive, arise suddenly fully developed—in the extreme form of the final stage of atrophic degeneration. There are cirrhoses and cirrhoses, and each has its successive stages of development. It is no doubt a subtle and secret malady—as a rule its existence is not suspected until it has reached such degree that grave symptoms have arisen to draw attention to its presence. But disease does not always proceed upon the lines laid down for it; is not rigidly bound by routine and red tape; is occasionally unorthodox; and cirrhosis now and again betrays itself at an earlier period of its course than the final stage prescribed for its disclosure. Symptoms, such as ascites, may anticipate the ordinary term and give opportunity for remedial treatment, so that in comparatively favourable although infrequent cases the patient may recover for a time of varying length—months or even years—and be afforded a respite of appreciable value.

It is my purpose to deal mainly with the three chief forms of cirrhosis and those with which ascites in its most pronounced and characteristic form is specially associated. It is on those distinguished as atrophic cirrhosis, hypertrophic cirrhosis, and syphilitic cirrhosis—that the main interest of the subject centres. Before proceeding further, however, it will be well to clear the ground by putting aside certain minor forms which lie outside the strict lines of the present inquiry. Amongst these are those conditions of fibrosis which are due to the obstruction of venous escape from the hepatic vein—as in mediastinal tumours, mediastinitis—or associated with general dropsy in mitral and tricuspid disease of the heart. The hepatic fibrosis which is set up by chronic venous congestion of this kind, is, as a rule, only slight cirrhosis, not usually sufficient in itself to interfere materially with nutrition, or to cause such serious portal obstruction as to give rise to abdominal dropsy. The peritoneal effusion is not great, and forms merely a part as it were of the general dropsy which follows the damming back of blood in the systemic venous system. Yet in some instances of this congestive cirrhosis we meet with an ascites as a distinct feature which is out of all proportion to the effusion elsewhere—not merely a part of general dropsy, but a special effusion into the peritoneal cavity—a true ascites due to added difficulty in the portal area; the systemic obstruction, insufficient alone to produce a general dropsy, reinforced by the *hepatic* obstruction causing *peritoneal* dropsy. I wish to draw attention to this because it has, I think, an important bearing upon certain cases of hypertrophic cirrhosis of which I have to speak later. The condition of pure cardiac cirrhosis considerable enough to produce ascites is shown in the accompanying reproduction of a drawing (see Fig. 1) of a section from a case under the care of Dr. Penrose, to whom I am indebted for permission to use it. The great trio of representative hepatic fibroses, which have been distinguished as atrophic cirrhosis, hypertrophic cirrhosis, and syphilitic cirrhosis, all marked by the increased formation of fibrous tissue in the structure of the liver, in their perfect type differ in clinical character, course, and pathological anatomy each from the other.

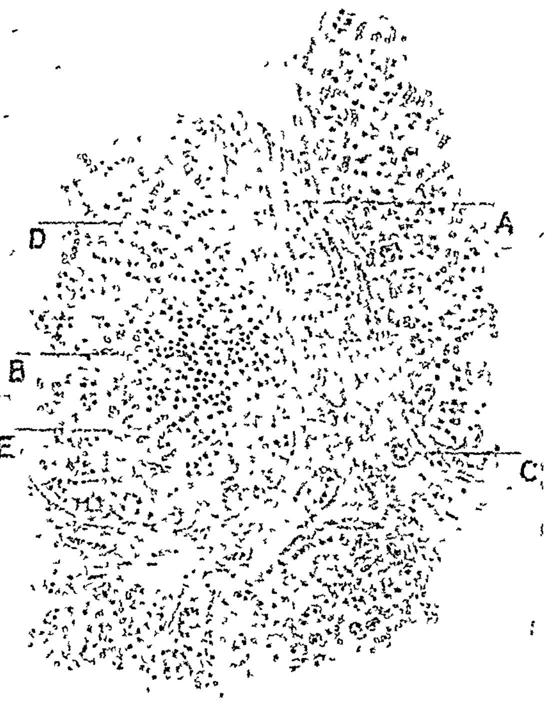
Although these things are familiar to all you will pardon me perhaps if, for the sake of greater clearness, I enumerate briefly the special characters which have been generally regarded as distinctive of each of the three cirrhoses.

---

[1] Lectures II. and III. will be delivered on April 3rd and 5th, 1900, respectively.

1. In atrophic cirrhosis the fibrous invasion is described as spreading along the main branches of the interstitial tree, embracing groups of lobules and compressing them, and thus causing atrophy and destruction of cells. The new fibrous growth between the enclosed groups of lobules contracts, and drawing in the surface at these points causes hobnailing of the surface and shrinkage of the whole organ, so that it is much smaller than normal, decreased in weight, tough, and hard. Amongst the clinical features which are laid down as characteristic of atrophic cirrhosis as contrasted with other forms are signs of portal obstruction, evidenced by the frequency of ascites and the occurrence of hæmorrhage from the stomach and bowels, the rarity of jaundice, the short course of the disease after it can be recognised, its inevitable fatality, and that it is almost invariably set up by chronic alcoholic irritation—atrophic multilobular cirrhosis or hobnail liver.

FIG. 1.



Hypertrophic cirrhosis of the liver due to long venous congestion from tricuspid incompetence A, Coarse fibrosis. B, Commencing fibrosis. C, Pseudo ducts D, Blood. E, Liver substance showing fatty change.

2. In the second form of cirrhosis—the hypertrophic form—described by Hanot as "biliary cirrhosis"—the liver condition is stated to be characterised by increase in size and weight. The fibrosis which invades the interstitial tree affects the smaller twigs rather than the main branches, embracing single lobules, and even single cells, instead of groups of lobules, accompanied, moreover, by a curious development of biliary canaliculi at the periphery of the lobule, due either to the formation of new ductules there or to the exposure of existing ones by denudation through the destruction of hepatic cells. In this form the liver is greatly enlarged, it is hard, smooth of surface, or only slightly granular—hypertrophic monolobular ciliary *cirrhosis.*

The clinical aspect of hypertrophic cirrhosis as laid down by authority is characterised by features which contrast sharply with those of the atrophic form. Ascites is described as entirely absent, or, if present, so slight as to be comparatively unimportant, while jaundice on the contrary is said to be an almost invariable symptom and is often intense and persistent. Intermittent attacks of pain and pyrexia, enlargement of the spleen, and a liability to the supervention of acute symptoms, such as severe delirium, hæmorrhages, coma, and a chronic course of some years, are other signs which are said to distinguish hypertrophic cirrhosis. Its cause is involved in obscurity; a doubtful factor, in some instances supposed to be malarial, in some alcoholic, in some obstruction to ducts, is credited with setting up inflammation of the biliary canaliculi, which is regarded as the starting-point of the pathological change.

3 The third variety of cirrhosis—the syphilitic—is described as characterised by the presence of broad bands of fibrous tissue separating isolated masses of liver tissue and causing destruction of hepatic cells. The organ is often much deformed by the gradual contraction of these several fibrous bands giving it a lobulated appearance, its surface is marked by rounded bosses, often scarred and furrowed, or only slightly uneven; gummata may also be present in various stages. A hard liver, usually enlarged, sometimes contracted, with uneven, bossed, or slightly irregular surface.

The clinical features of this kind of cirrhosis closely resemble one or other of the preceding forms—in the early stage of enlargement the hypertrophic and in the later either the hypertrophic or atrophic alcoholic form. In one case there is jaundice but no ascites; in another there are both; in a third there is neither, but, as a rule, when advanced, ascites and *perihepatitis. There is another form of syphilitic* cirrhosis described as chiefly limited to the hereditary syphilis of childhood—a diffuse fibrosis, characterised microscopically by its immature, partly cellular, character, penetrating the lobules and even between the cells. The liver is greatly enlarged—clinically, jaundice, ascites, and emaciation are amongst the chief symptoms.

POINTS IN THE PATHOLOGY AND CLINICAL HISTORY OF THE CIRRHOSES NOT YET FINALLY DECIDED.

Although there is a tolerably consistent general agreement as to the main features of the morbid anatomy of cirrhosis there is still some confusion as to the relation of the different changes to clinical conditions; discrepancies of opinion on certain points of etiology; divergent views as to the symptoms and course of the disease in its different forms. Amongst the questions awaiting an accepted and final settlement are the following. Is atrophic cirrhosis—i.e., the contracted hobnail liver—always of alcoholic origin? Is the liver small from the first or is there an earlier stage in which it is enlarged, becoming contracted later? Or is atrophic cirrhosis merely a late stage of hypertrophic cirrhosis? Or is there an alcoholic cirrhosis in which the liver is hypertrophied and enlarged from first to last? Or is hypertrophic cirrhosis limited to the biliary cirrhosis of Hanot and Charcot of uncertain origin? Or it is even asked, Does the biliary form described by French authorities exist at all as a distinct entity? Again, is ascites practically limited to the atrophic form—almost unknown in the hypertrophic? and, on the other hand, is jaundice rare in atrophic cirrhosis—almost invariable in the hypertrophic form? Are the microscopic characters of monolobular cirrhosis, with hyperplasia of the bile-ducts, as described in the biliary hypertrophic cirrhosis of Hanot and Charcot, found only in cases which correspond to that clinical type? or are they met with in both atrophic and hypertrophic cirrhoses of alcoholic origin? The part played by alcohol, syphilis, and malaria in causation and their connexion with special types of affection; the incidence and significance of perihepatitis, the curability of ascites, the efficacy of paracentesis or its uselessness in the treatment of it, the possibility, not of curing cirrhosis, but of prolonging the life of the cirrhotic patient by this and other means, the conditions under which the course of cirrhosis can be favourably influenced in this way—are other points upon which there is a general agreement. It is to some of these questions that I shall endeavour to find an answer.

FACTORS IN THE CAUSATION.

Atrophic cirrhosis of the contracted hobnailed liver would appear to be almost invariably of alcoholic origin. It is said that malaria sometimes plays a part in its production, but the evidence of this is by no means conclusive. I have met with no instance of the kind; yet it is not intrinsically improbable that a disease like malarial fever which sets up such marked fibrosis of the spleen should also set up an analogous fibrosis of the liver. In those cases attributed to malarious influences, however, when the cirrhosis is of the contracted hobnailed variety, at all events it is probable that alcohol, an agent by no means inactive in malarial districts, is largely concerned in its production.

The Question of an Early Stage of Enlargement in the Atrophic Form.

Another question which has been much debated is, Is the liver enlarged in the early stage of atrophic cirrhosis? Is it first hypertrophied and subsequently diminished in size as fibrotic contraction proceeds? The older writers generally held that this was so occasionally but that it was exceptional. Murchison[2] expressed the opinion that it was a matter for further investigation whether, if a patient with enlarged liver survived long enough, the enlargement would be followed by cirrhotic contraction? In one case reported by him in which the liver was greatly enlarged from cirrhosis attributed to alcohol and malaria the organ was found to be of its natural size three years later. The patient was treated with mercury, however, and it is doubtful if the condition was one of simple alcoholic cirrhosis. The patient got well and the decrease of size ceased at the normal level.

Instances have been recorded by Dr. Frederick Taylor and others[3] in which the greatly enlarged liver of alcoholic cirrhosis has been observed to undergo contraction. I have watched a number of these cases of cirrhosis with enlargement for considerable periods—one for nearly 12 years, one for eight years, and one for two years. In the first there has been some slight decrease in size, but great enlargement is a characteristic feature still, and in no case have I observed the condition change from an enlarged to a small contracted liver. I think, however, that there is a stage of engorgement and congestive swelling in the atrophic cases before fibrotic contraction is fairly in process. We are all of us familiar with the enlarged liver of the drinker who has not developed any symptoms of actual cirrhosis. This, however, is quite distinct from the large, hard liver of hypertrophic cirrhosis, which does not merge into the atrophic form. Such contraction as that described in Dr. Taylor's case must at least be extremely rare. The hypertrophied liver does not regularly represent the early stage of the contracted form. The microscopic characters alone negative this—in the one the fibrosis multilobular almost invariably, in the other monolobular or a combination of the two. Hanot, indeed, recognised that hypertrophic cirrhosis of alcoholic origin was not merely an early stage of the atrophic form.[4]

The error of regarding the hypertrophic and atrophic condition as different stages of the same thing has probably arisen from its being observed that in some cases the liver was large and that in others it was small; and since a permanent hypertrophy was supposed to be limited to Hanot's biliary form the inference was too hastily drawn that in alcoholic cirrhosis the large and small were connected and merely different stages of the same affection. They are distinct varieties, rather than different stages of alcoholic cirrhosis.

Ascites in Atrophic Cirrhosis—its Significant Viability in Atrophic Cirrhosis

In the next place, Is the occurrence of ascites a special feature of atrophic cirrhosis and practically limited to the final stage of it? and is it as rare in the hypertrophic form as it is common in the atrophic? There can be no doubt as to the frequency of ascites in atrophic cirrhosis. In 23 consecutive cases of fatal cirrhosis at St. Mary's Hospital in which the liver was small (under 60 ounces) ascites was present in 17 cases and absent in six only. Nor can there be any question of its grave significance in the majority of cases. It indicates generally that the disease has progressed towards its end—that the collateral circulation established has become inadequate to the full relief of the obstructed portal circulation and that the destruction of liver tissue, advancing usually *pari passu*, has reached the limit of viability. As a rule, but by no means invariably, the patient has only a few months to live; now and again, however, the months are extended to a year or two. As a matter of fact, the supervention of marked jaundice in atrophic cirrhosis is of more immediately fatal augury than the appearance of ascites. There are cases of atrophic cirrhosis in which ascites supervenes before the final stage, when sufficient glandular structure still remains intact and functionally effective to carry on life, and the obstruction to the portal system is not yet so great as to be past compensation by collateral channels, so that partial recovery may take place for a time.

The stage of the liver change at which such survival for a time, after the advent of ascites, is possible, is illustrated by the case of a woman admitted to St. Mary's Hospital for hæmatemesis and ascites in October, 1891. She was a confirmed spirit drinker. She was tapped three times at intervals and recovered her general health sufficiently to return to her usual home life, but came into hospital more than a year later with acute bronchitis from which she died. Post mortem the liver was found to be moderately hobnailed, small, but microscopically a large portion of liver tissue, calculated at about one-half, was found to be normal and presumably effective. Her condition, although vulnerable, was still viable under favourable circumstances. I might adduce a number of other examples which show in like manner that the occurrence of ascites in atrophic cirrhosis is not always such sentence of immediate death as is commonly inferred. This evidence will, however, be brought forward more appropriately when I come to speak of prognosis.

The Occurrence of Jaundice in Atrophic Cirrhosis.

In the standard descriptions of the symptoms pertaining to atrophic cirrhosis a point is made of the fact that although a slight icteric tint may be present, marked jaundice is conspicuously absent as compared with its almost invariable presence in the hypertrophic form. Here, again, we have been misled by the assumption that hypertrophic cirrhosis usually corresponds with Hanot's special biliary form. The matter is of no great moment, but no such hard-and-fast line as to the occurrence of jaundice can be drawn. Jaundice of a marked character is not consistently absent in the small liver of alcoholism, and on the other hand it is by no means constantly present in the hypertrophic form; Murchison[5] observed that although decided jaundice is rarely met with in atrophic cirrhosis in the early stage it may occur in advanced stages and is then an ominous symptom. Dr. Foxwell,[6] as the result of his investigation of 67 cases, concludes that jaundice and cerebral symptoms are as common when the liver is small as when it is large. In 53 fatal cases of cirrhosis of all kinds at St. Mary's Hospital during the last ten years I find eight in which marked jaundice was observed. In four of these cases the liver was small and in four enlarged. The distinction between the two forms with regard to the occurrence of jaundice should be, that whilst it is met with pretty equally in both forms, it occurs at an earlier stage in the hypertrophic than in the atrophic condition, in which latter it is often indicative of the approach of a fatal termination.

The Character of the Fibrosis in Atrophic Cirrhosis.

Another question of some interest in connexion with atrophic cirrhosis is whether the fibrosis is always of the coarse multilobular kind, affecting the main branches of the interstitial tree, or whether the finer interlobular variety, which is undoubtedly most characteristic of the hypertrophic form, is found in the small contracted liver also. In the 53 cases adduced the liver was specially examined microscopically in 18 In one only of the distinctly contracted specimens was the fibrosis diffuse; in the rest it was coarse and multilobular In a few instances a small amount of finer fibrosis was observed invading the lobules.

The Association of Atrophic Cirrhosis and Bright's Disease.

A certain amount of interstitial change is found in the kidneys in a large proportion of cases (about one half) of alcoholic cirrhosis In most it is not extreme; and this fibrosis of the kidney is to be regarded as a result of alcoholism—just as is the fibrosis of the liver—the kidney being affected usually in minor degree. In some cases the interstitial nephritis is advanced and, associated with the Bright's disease, a special form of cirrhotic atrophy is occasionally found which has been more particularly described by Dr. C. H. Fagge and Dr Hale White. In this the liver is greatly contracted, its substance is atrophied, but the connective tissue is not always greatly increased. The capsule is much thickened, and there are also extensive perihepatitis and associated adhesive peritonitis and ascites, which are attributed chiefly to the perihepatitis and chronic peritonitis. This condition of perihepatitis and chronic peritonitis is well exemplified by a case that was under my care in 1896.

[5] Diseases of the Liver, second edition, p. 123

[6] Birmingham Medical Review, vol. i, 1896.

A woman, aged 50 years, had been a patient at intervals for the previous 12 months for ascites and had been tapped nine times. The last operation proved fatal owing to septic peritonitis. The stomach and intestines were thickened and adherent from old peritoneal inflammation of which the hepatic region was the chief centre. The liver was small, surrounded by a thick, false membrane, moderately cirrhosed, weighing 40 ounces. The kidneys were extremely granular.

This same condition of perihepatitis and dry peritonitis with adhesions occurs, however, in atrophic cirrhosis apart from Bright's disease. In one case, that of a patient (Dec. 2nd, 1898) who was tapped 11 times, there were perihepatitis, chronic peritoneal adhesions, perisplenitis, and thickening of the intestines with advanced cirrhosis; the liver weighed only 33 ounces, but the kidneys were normal.

In another still more extreme case under my care, that of a woman, aged 39 years, a confirmed gin drinker, this condition of perihepatitis and associated adhesive peritonitis was equally marked. She was admitted first in July, 1893, for ascites and peripheral neuritis; she was tapped twice, discharged relieved, and admitted again six months later for the same trouble; she was again tapped twice and discharged relieved; she was admitted a third time one year later and again tapped. On this occasion, however, suppurative peritonitis followed, apparently from fouling of the drainage tube; which was accidentally displaced and the case ended fatally. The post-mortem examination revealed extreme perihepatitis with thickening and adhesion of adjacent intestines and advanced cirrhosis of the liver, which was typically hobnailed and which weighed only 18 ounces. The kidneys were not affected.

In the 53 cases mentioned there are 15 in which extensive perihepatitis is recorded, usually with extension of peritonitis and adhesions to neighbouring structures, notably the diaphragm, stomach, and transverse colon. Of these 15 four were syphilitic; in one of these parenchymatous nephritis was present; in the remaining three the kidneys were normal. Of the 11 others, in four the kidneys were more or less granular, in three they were enlarged, and in five they were normal. In 22 cases of the 53 the perihepatitis was slight or not recorded. In four cases there was acute peritonitis. Of these the kidneys were fibrosed in three; in one (which was syphilitic) there was cloudy swelling. In five of the 53 cases there was some chronic peritonitis other than perihepatitis. Of these in one the kidneys were granular, in two they were large and tough, and in two they were not affected. In six of the last cases examined in which the condition was specially noted it is stated positively that there was no peritonitis In five of these the kidneys were cirrhotic; in one they were congested only.

Since therefore in these cases of cirrhosis with extensive perihepatitis and adhesive peritonitis of neighbouring structures the kidneys are not constantly affected and, on the other hand, when the kidneys are granular there may be no peritonitis, the presumption is that the cirrhosis, perihepatitis, and Bright's disease are probably due to the same cause—chronic alcoholic poisoning. As I shall show later the most marked instances of perihepatitis and related peritonitis which I have seen have been in connexion with syphilitic cirrhosis, in which connexion Murchison also observed it.

HYPERTROPHIC CIRRHOSIS.

The first question which arises with respect to cirrhosis with enlargement of the liver, is whether the affection described by Hanot and Charcot as a biliary cirrhosis of uncertain origin is to be accepted as the representative form of hypertrophic cirrhosis, or if it exists even as a separate entity or is merely a modified form of alcoholic cirrhosis. It will be remembered that hypertrophic cirrhosis is described as having a special morbid anatomy and a distinct clinical history and course which give it a marked individuality of its own. I think that we have been unduly biased by the classical description of Hanot, as we were formerly by Laennec's description of the atrophic form, and have had no eyes to see obvious facts. Just as deference to Laennec's authority led to the too ready assumption that an enlarged fibrosed liver must be an early stage of the atrophic form, so, when the existence of a distinct hypertrophic condition, always hypertrophic, and of special character was demonstrated it was assumed that every cirrhosis with enlargement must conform to this special variety. It is surprising how a definite observation of this kind, stated with authority, holds sway, and its general application long remains unquestioned, as all-comprehensive, without further examination or inquiry. Subsequent research, however, has proved that many of the features which were considered to be distinctive of the so-called biliary cirrhosis are not peculiar to that exact type, but occur also in cirrhoses which in other points do not conform to Hanot's description.

THE CHARACTER OF THE FIBROSIS.

Thus, for example, there is now no question that a fine fibrosis, monolobular or intralobular in arrangement, occurs in conjunction with hypertrophy of the liver in cirrhosis due to alcohol; and this diffuse fibrosis appears also to be met with in the cirrhosis attributed to malaria which is usually hypertrophic and in pure cardiac cirrhosis.[7] It is also established, I think, without question that the appearance of hyperplasia of bile ducts in the highly nucleated tissue between the lobules is not met with in cirrhosis with the clinical characters of Hanot's form alone. Dr. R. Saundby[8] has shown that this appearance of new canaliculi occurs in cases of ordinary cirrhosis, and also that it is not always present in any marked degree in cases presenting the clinical characters of biliary cirrhosis. Dr. Frederick Taylor has produced evidence of a like nature,[9] In a case of alcoholic cirrhosis with enlarged liver recently under my care this appearance was found in conjunction with a coarse fibrosis and in another instance a fine fibrosis was observed in a case of alcoholic cirrhosis without jaundice in which the liver was not enlarged, weighing 53 ounces. This same formation of so-called biliary canaliculi is also seen in the simple fibrosis of heart disease as shown in the illustration (see Fig. 1). The interstitial fibrosis most commonly met with in cirrhosis in which the liver is enlarged is a combination of coarse multilobular and fine monolobular development. The microscopic distinction therefore does not hold.

THE OCCURRENCE OF JAUNDICE.

In the next place, the presence of jaundice is by no means a constant or, according to my experience, a very common symptom of hypertrophic cirrhosis. In 17 consecutive fatal cases of cirrhosis with enlarged liver, varying in weight from 60 to 134 ounces, I find jaundice noted as a marked symptom in four only; in six it is described as slight, and in the remaining seven none is recorded. Again, out of 27 more cases of cirrhosis with enlarged liver in which the patients have either recovered or have been relieved or in which, if fatal, no post-mortem examination was made, jaundice was absent in 19 and present only in eight. In 10 cases of enlarged fibrous livers from different causes recorded by Murchison jaundice is mentioned as a symptom in four only, and, as noted before, Dr. Foxwell's investigation of 67 cases of cirrhosis yielded the conclusion that jaundice was as common when the liver was contracted as when it was enlarged.[10] It is clear, therefore, that jaundice is by no means a constant or characteristic symptom of hypertrophic cirrhosis generally; and, on the other hand, as we have seen before, jaundice in marked degree is by no means rare in the atrophic form.

ASCITES IN THE HYPERTROPHIC FORM.

Again, in the typical form of hypertrophic biliary cirrhosis the absence of ascites in any important degree is described as being as distinctive a feature as the presence of jaundice. This certainly does not hold good with regard to the hypertrophic cirrhosis which has come under my observation. In the 25 fatal cases of hypertrophic cirrhosis in which the liver weight varied between 60 and 134 ounces ascites was present in 16. In six which recovered more or less perfectly ascites was a prominent symptom in all but one. In the 10 cases of hypertrophic cirrhosis given by Murchison ascites was present in seven. Bristowe records one of alcoholic cirrhosis with great enlargement in which the patient was tapped 14 times for ascites. In the 67 cases of alcoholic cirrhosis recorded by Dr. Foxwell he found that ascites was as common when the liver was large as when it was small. The absence of ascites, therefore, is not a constant and typical negative symptom of cirrhosis when the liver is enlarged, any more than the presence of jaundice is a reliable sign or distinctive symptom of the hypertrophic form. It is, I think, probable that this impression of the frequency of the occurrence of ascites in contracted liver, and its absence in the enlarged liver, has arisen partly from the fact that atrophic cirrhosis escapes notice until ascites arises to draw attention to it. A liver smaller than natural is not obtrusive. When the liver is enlarged, however, it challenges recognition and is often discovered before ascites supervenes. *Enlargement of the spleen, again, is not an especial feature* of hypertrophic cirrhosis. In the 53 cases which I have instanced it was enlarged in the great majority of alcoholic cirrhoses, both large and small; but the greatest size was reached in the syphilitic cases, in one of which it attained to 42½ ounces, or six times the normal weight.

PAIN AND PYREXIA; SUPERVENTION OF DELIRIUM, COMA, AND THE TYPHOID STATE.

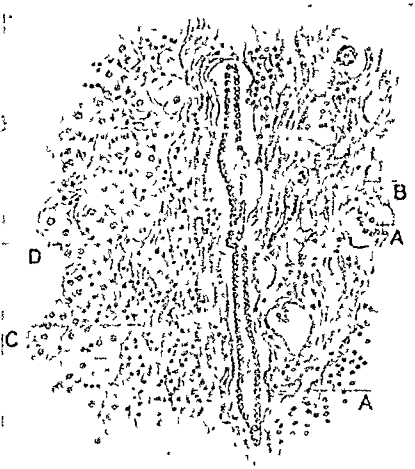
Another feature which is said to mark the course of biliary cirrhosis is the occurrence of attacks of pain and pyrexia. These symptoms are not, however, peculiar to cases of the kind. They are met with in atrophic cirrhosis,[11] in alcoholic hypertrophic cirrhosis without the characteris*tics of the biliary form, and notably in syphilitic cirrhosis.*[12] *Pain, tenderness, and pyrexia are, I imagine, merely* an indication of the supervention of perihepatitis. The charts show the pyrexia, coexisting with pain and tenderness, which mark the presence of perihepatitis in all forms of cirrhoses. Grave symptoms, such as delirium, the typhoid state, and coma, are not confined to hypertrophic cirrhosis of the so-called biliary type. They occur in hypertrophic cirrhosis of alcoholic origin and type and, as Murchison noted, and as I have seen, in atrophic cirrhosis also. These symptoms cannot therefore be regarded as distinctive of special forms of hypertrophic cirrhosis.

THE CHRONIC COURSE.

Lastly, the *course of the typical form of hypertrophic* cirrhosis is stated to be a chronic one of two, four, or six years, or more. It must be allowed that the cases which run a protracted course are those in which the liver is enlarged; they are as a rule more benign. This is, however, not invariable, and Dr Dreschfeld[13] has recently published a case of alcoholic hypertrophic cirrhosis which, while agreeing with Hanot's affection in many respects, differed in the presence of ascites, and in the short course of the disease. Chronicity then cannot be regarded as a constant character of hypertrophic cirrhosis.

It will be seen therefore that a cirrhosis in which the liver is greatly enlarged may fail to correspond in one case or other in nearly every particular with the classical type *for which we all look and so rarely find. Further, from* the time of Murchison downwards a number of cases of cirrhosis have been recorded by Saundby, Bristowe, Dreschfeld, Foxwell, and others in which, although the liver was greatly enlarged, the symptoms have been those usually ascribed to the contracted liver, rather than those attributed to so-called biliary cirrhosis. And in the majority of instances the cause has been traced to alcoholic intoxication. A number of like cases have come under my own observation, the details of some of which I shall giver later. For the present I may say that the hypertrophic cirrhosis which I have met with corresponds with the cirrhosis of Hanot chiefly in two respects—viz., in the smooth, hard enlargement of the liver, and that the fibrosis is usually diffuse and monolobular and sometimes partly multilobular. In one instance, however, in which the liver weighed 152 ounces the cirrhosis was coarse and multilobular, with much fatty deposit. Is it, therefore, to be inferred that no such special form of hypertrophic cirrhosis *as that described by Hanot and recognised by Charcot* actually exists? I think that we are not warranted in assuming this absolutely. In addition to the original cases described so graphically by the French writers other isolated instances have been observed now and again in this country and abroad which agree closely with the so called biliary type. For my part I have not, in spite of a close scrutiny for 16 years, met with a case which has exhibited in full completeness the typical presentment of the French authorities. In three instances only have I seen any close approximation to it. One of them occurred in a boy aged eight years who was admitted for jaundice, enlarged liver, and ascites, and who died from exhaustion and emaciation four years later. He had had repeated attacks of jaundice since birth. Post mortem a smooth large liver was found weighing 60 ounces, with fine diffuse fibrosis, abundant nuclear growth, and imperfectly formed fibrous tissue. There was extensive perihepatitis, and the vessels of the portal fissure were found to be matted together, the cystic and hepatic ducts being reduced to mere cords and quite impervious. In another example[14] in which the patient was admitted for abdominal pain and jaundice which had existed on and off for six years the liver was enlarged to the level of the umbilicus. The spleen was also enlarged and ascites was present. Post mortem the liver was slightly granular and it weighed 80 ounces. The common bile duct was found to be enormously dilated from blockage by two large gall-stones. Microscopically the fibrosis was seen to be fine, with some coarse strands in which pseudo ducts were conspicuous (see Fig. 2).

FIG. 2.



Diffuse hypertrophic cirrhosis of the liver associated with obstruction of the common bile-duct by gall stones. A, Pseudo duct. B, Coarse fibrosis C, Fine fibrosis. D, Liver cells.

These two cases are especially interesting, because they correspond in most respects with results obtained experimentally by the ligature of the common duct in animals. They differ from Hanot's form chiefly in the existence of ascites and the occlusion of the duct. Cases of cirrhosis associated with gall-stones have been recorded by Dr. S Mackenzie,[15] Mr. D'Arcy Power,[16] and others. The fact remains, however, that in the majority of cases of obstructive jaundice, even when prolonged, no cirrhosis follows.

The third case was that of a man aged 42 years (Case 8, 1898), an indoor servant and heavy drinker, whose *face bore testimony to his habits,* who was admitted with deep jaundice of five weeks' duration, delirium, and pyrexia, and who died on the next day; there was no ascites Post mortem the liver was found to be greatly enlarged, weighing 114 ounces; it was smooth, bile stained, free from perihepatitis, and the *structure showed a fine fibrosis of* ill-formed nuclear fibrous tissue. Many of the hepatic cells were destroyed; the others were fatty. The kidneys were slightly granular and fatty. *Here again the disease was* not chronic or the jaundice of long standing, and the cause was alcoholic.

Although in view of the detailed description of such cases occurring in the experience of others it must be allowed that, clinically at all events, cirrhosis of that precise character does arise from time to time, it is certain that it is rare, at least in this country. It is, moreover, still doubtful whether these rare examples are entirely distinct from hypertrophic cirrhosis of alcoholic origin or are merely an exceptional variety of it. At all events, the representative fibrosis of the liver with enlargement is, in the vast majority of cases, a hypertrophic cirrhosis set up by alcohol equally with the atrophic form, in other instances by syphilis, and not the rare condition described by the French pathologists.

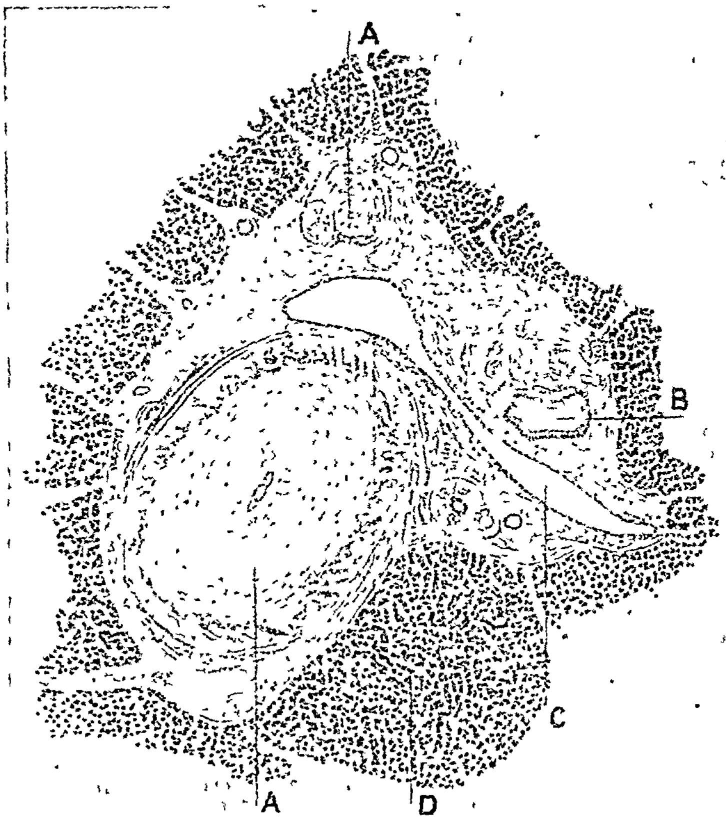
SYPHILITIC CIRRHOSIS.

The points at issue with regard to syphilitic cirrhosis are comparatively few. The ordinary form which results from acquired syphilis in the tertiary stage has usually well-marked characteristics when the liver is examined after death, although its identification during life is often extremely difficult and mistakes in diagnosis are frequent with regard to it. In a typical instance the gummata in various stages, the massive wedges penetrating the liver substance at various points, the scarring and puckering and lobulation, and the extensive perihepatitis are striking and unmistakeable morbid appearances. Microscopically may be seen the gummatous cellular growth developing into fibrous tissue or undergoing caseation. In the specimen represented here, for which I am indebted to my friend Dr. Poynton, there is seen also well-marked endarteritis obliterans—a condition well known as the result of tertiary syphilis elsewhere, but, as far as I am aware, not observed directly in connexion with hepatic syphilis, until it was noted in this case by Mr. Plimmer, our able pathologist at St Mary's Hospital (see Figs. 3 and 4). In a paper by Hanot and Chauffard[17] this condition of arteritis is described, and drawings of it given, as met with in hypertrophic cirrhosis with pigmentation and diabetes, to which latter affection the cirrhosis was regarded as secondary. In one case, however, scarring is mentioned, a condition which is very suggestive of syphilitic affection. In the second case, it is said, there was no history of syphilis and the surface of the liver was flat and finely granular.

FIG. 3.



Syphilitic cirrhosis of the liver showing endarteritis obliterans of the hepatic artery in a portal vein. A, Endarteritis obliterans in various stages. B, Bile-duct C, Portal vein D, Liver substance.

One point which is not sufficiently recognised and which I would emphasise is that the morbid changes in syphilitic cirrhosis may exist in every degree. Occasionally they are so slight as scarcely to alter the normal appearance of the organ; a few small scars, some thickening of the hepatic capsule, or slight perihepatitis, may be the only morbid features perceptible externally on post-mortem examination. This fact is of great importance in its bearing upon diagnosis. There may be no suspicious history, nothing whatever distinctive in the physical signs made out during life. The condition of the liver, as ascertained by examination of the abdomen, may correspond exactly with that of an ordinary alcoholic cirrhosis. Another feature of syphilitic cirrhosis is the degree of perihepatitis and local peritonitis in the region of the liver. This condition of general perihepatitis with extension to neighbouring structures is far more marked in connexion with syphilitic disease than in any other condition. The four most notable examples which I have met with, as I stated previously, have been in this relation.[18] In these the kidneys were normal except in one instance when there was parenchymatous nephritis. In the most extreme of all[19] the liver was studded with gummata in various stages, the capsule being covered with thick coating and adherent to the diaphragm, the abdominal wall, and the transverse colon. The stomach and spleen were bound down by adhesions and the liver and adjacent viscera were glued together in an inseparable mass. The liver was clearly the centre from which all the neighbouring peritonitis had spread. The kidneys were absolutely healthy, yet there was no history of syphilis. The man was married and had healthy children.

[17] Revue de Medecine, 1882. "Cirrhose Hypertrophique pigmentaire dans le diabète."

[18] A. B., liver weight 134 ounces; C. D., liver weight 60 ounces; E. F., liver weight 88 ounces, G. H., liver weight 58 ounces.

[19] G. H.

This point of the great development of perihepatitis and local peritonitis in many cases of syphilitic cirrhosis has been imperfectly recognised. Perihepatitis has been usually regarded as more especially associated with other forms. Murchison, however, observed that it was met with in marked degree in syphilitic cirrhosis and in connexion with long-standing disease of the heart. He described it as accompanied by fibrous bands extending from the capsule into the liver structure and causing atrophy. The fact of the association of extensive perihepatitis and local peritonitis with syphilitic cirrhosis is of considerable clinical importance. There may be, as I have observed, no history of syphilis in these cases. In 10 cases of which I have notes—eight of which were fatal, the gummata being found post mortem—in two only was there any definite history of syphilis; in two others syphilitic scars were found during life, but distinctive physical signs in the shape of irregularities or bossing of the surface were found in three only. The usual condition disclosed by physical examination of the abdomen was a large liver, smooth and slightly irregular and hard, or sometimes simply that the liver was small and contracted.

The syphilitic liver, then, is liable to be mistaken clinically, and as a matter of fact is, I believe, frequently mistaken, for the alcoholic liver, an error which in view of the remedial power of anti-syphilitic remedies may be a disastrous one. Let me repeat that one helpful symptom in such cases is the existence of signs of perihepatitis, pain, and tenderness over the liver, and pyrexia. When these exist in marked degree and are at all persistent they afford a presumption in favour of the syphilitic nature of the affection. The charts of temperature afford valuable indications of the existence of perihepatitis. Perihepatitis does occur in pure alcoholic cases, and in connexion with Bright's disease, but, according to my observation, it is not so constant or so extreme as in syphilitic cirrhosis.

Another undetermined question is as to the specific cirrhosis which arises in young children as a result of congenital syphilis. I have not met with any instance of gummatous development such as is found in the acquired disease, although it has been described by Ziegler and others. The smooth liver greatly enlarged offers no points of distinction from a liver enlarged from other causes, and the diagnosis must depend upon the history or the existence of other signs of the disease.

Post mortem the microscope reveals a very distinct form of cellular infiltration and early fibrosis which spreads through the lobule between the cells in a diffuse and characteristic manner. There may be no thickening of the capsule or external change perceptible.

In eight cases of cirrhosis in children between five and nine years of age of which I have careful records there was a reliable history of congenital syphilis in two only. In two there was one of alcoholism and in the remaining four no cause could be made out. In connexion with this subject of cirrhosis in children there are many interesting points—such as the effect of congenital obliteration or stenosis of the bile-ducts as recorded by Dr. John Thomson,[20] the question of hereditary tendency as noted by Dr. Howard[21] and Dr. Finlayson,[22] and the connexion of this with nervous lesions. I think it is probable that congenital syphilis will furnish the key to the relation of these several conditions. With these matters, however, it is beside my present purpose to deal.

The Goulstonian Lectures

ON

THE TYPHOID BACILLUS AND TYPHOID FEVER.

Delivered before the Royal College of Physicians of London on March 20th, 22nd, and 27th, 1900,

BY P. HORTON-SMITH, M.A., M.D. CANTAB., F.R.C.P. LOND.,

ASSISTANT PHYSICIAN TO THE BROMPTON HOSPITAL FOR CONSUMPTION AND TO THE METROPOLITAN HOSPITAL, ASSISTANT MEDICAL TUTOR TO ST BARTHOLOMEW'S HOSPITAL.

LECTURE II.[1]

Delivered on March 22nd.

MR. PRESIDENT AND GENTLEMEN,—In my first lecture I discussed the bacteriology of an ordinary case of typhoid fever. To-day I desire to consider abnormal varieties of typhoid infection, and the relation which the bacillus bears to the chief complications and sequelæ of the disease. Before, however, passing to this subject it will be well to turn our attention for a short time to the question of relapses, for recent work enables us to offer at least a partial explanation of this interesting condition.

RELAPSES IN TYPHOID FEVER.

In the first place it must be allowed that a relapse is nothing less than a complete renewal of the primary disease. As a rule the whole cycle of changes met with in the first attack is again passed through. Thus fresh intestinal lesions are produced and a second generalisation of the bacilli occurs, as evidenced by the recurrence of the typical eruption. Indeed, the only difference which can be noticed between the attack and the relapse is that, as a rule, the duration of the latter is somewhat less than that of the former, though even in this respect exceptions are by no means uncommon. How, then, are we to explain this complete re-infection, at a time, too, when the protection acquired by the former attack has already begun to manifest itself? The experiments of Chantemesse and Widal and of Sanarelli throw light on the matter.

It is well known that the typhoid bacillus, whether isolated from the tissues after death or obtained from the stools or urine during life, has, for animals at least, but a low degree of virulence. If injected in large quantities into the peritoneal cavity of a guinea-pig it is capable of causing death; subcutaneously, however, as a rule it is without effect. Chantemesse and Widal,[2] however, show that if in addition to injecting the bacillus subcutaneously the toxines of the streptococcus pyogenes are injected intra-peritoneally, then the virulence of the typhoid bacillus becomes greatly increased, so that after several such passages the typhoid bacillus finally becomes so pathogenic that even by itself, without the aid of streptococcus toxine, a small quantity injected under the skin is sufficient to cause death within 24 hours from general typhoid septicæmia.

The toxines of the streptococcus, however, are not the only soluble poisons which, by diminishing the resistance of the organism, allow of the rapid growth and increased virulence of the typhoid bacillus. The toxines of bacillus coli and bacillus proteus vulgaris may be used instead, as Sanarelli[3] has shown. Now it is noticeable that these very micro-organisms, the toxines of which when absorbed so assist the growth and further the generalisation of the typhoid bacillus, are normal inhabitants of the human intestine. In addition, it is known that during typhoid fever they themselves, and especially the bacillus coli, rapidly increase in number, while their virulence becomes greater.[4] Lastly, in many cases of the disease their toxines *are* absorbed, for, as I shall show, it is by no means uncommon to find that the blood of a typhoid patient is also agglutinated by the bacillus enteritidis, while Lorrain Smith[5] has shown the same to be true for other varieties of bacillus coli, evidently proving that the toxines of these bacilli have been absorbed into the system.

It is evident, then, that these facts offer us a clue whereby to explain the occurrence of relapses. If in a given case at the end of the attack the immunising properties have been as yet but poorly acquired, only just in sufficient degree to destroy the majority of the bacilli but leaving others intact, and if under these circumstances a further absorption of toxines from the alimentary canal should take place, then we shall have all the conditions which will enable the typhoid bacilli to acquire fresh virulence and to re-invade the organism.

Further, the experiments of Sanarelli,[6] if they should be fully confirmed, seem to lift this view from the domain of theory into that of fact. Thus Sanarelli showed that it is quite easy to produce experimentally a relapse of the acute septicæmic typhoid fever from which animals in general suffer. All that is necessary is to inject into a guinea-pig at first a dose not quite sufficient to be fatal. The animal recovers, but for some time afterwards attenuated typhoid bacilli may still be found in the purulent focus at the seat of inoculation. If, now, in this condition a dose of toxines, either of bacillus coli or of bacillus proteus vulgaris, be injected into the peritoneum, the typhoid bacilli at once acquire fresh virulence, the organism is invaded afresh, and the animal dies from acute experimental typhoid fever. More important still, on two occasions he was able to determine such a relapse by injecting small quantities of the toxine into the stomach and so into the intestines, thus exactly reproducing the conditions occurring in the human [illegible]

It would seem, then, probable that auto-i[illegible] a very impor[illegible]t part in the causation [illegible] sideration [illegible]marked, in favour of [illegible] ment of the [illegible]sease and one which a[illegible] wisdom of the common practice of withh[illegible] some considerable time after the norm[illegible] been reached. If this be given too early, b[illegible] juices have recovered their full power, marke[illegible] changes would be likely to occur in the undigested [illegible]nd thus the conditions favouring a relapse would arise.

Is, however, the rôle played by auto-intoxication [illegible]nited to its connexion with relapses? May it not be of [illegible]al or even greater importance, as indeed Chantemesse and Widal suggest, in determining the primary disease? The knowledge which we now possess concerning the enormous numbers of bacilli which may be excreted from a patient suffering from typhoid fever renders it more and more evident that the typhoid bacillus is not the only factor necessary for the production of typhoid fever. Were it so no one should escape, least of all those who work at the disease. To originate the fever other factors must cooperate after the introduction of the bacillus. The gastric juice has no power to destroy the micro-organism and it therefore always passes into the intestine, and yet typhoid fever, as we see in cases of epidemics, by no means always results. May it not be that, in some cases at least, disease only follows when as the result of some trifling derangement of the bowel the soil has already been prepared by the absorption of toxic products or, in other words, by auto-intoxication?

TYPHOID FEVER WITHOUT INTESTINAL LESIONS.

In my first lecture, after discussing the relation which the bacillus bore to an ordinary case of typhoid fever, I showed that the evidence pointed convincingly to the view that the disease was really of the nature of a septicæmia—modified septicæmia, it is true, in that in nearly all cases the primary lesion is in a definite situation, but septicæmia none the less, in that in all cases the generalisation of the bacilli through the blood takes place, with the subsequent growth of the organism in the most diverse organs of the body. Closely connected with this more modern view of the disease is a question which has lately been exciting much interest, whether, namely, it is possible to have typhoid fever without intestinal lesions—to have, in fact, a typhoid septicæmia without a marked primary focus of disease. Evidently, from what has been said, there would seem to be nothing to prevent such a variety of the disease occurring. Indeed, we might go further and say even that we might expect it. The question is one which can only be settled finally by bacteriology, but it should not be forgotten that in reality this is no new idea It is, indeed, as old as our knowledge of typhoid fever itself Thus Louis[7] records among his cases one (Observation 52) in which, while clinically the case seemed undoubtedly one of typhoid fever, yet post mortem there were no intestinal lesions It is true that he himself refused to believe that this and similar cases were really typhoid fever, but such was not the opinion of all his contemporaries. Since the time of Louis, also, many similar cases have been reported from time to time, and of late years a certain number with bacteriological examinations. In all some 18 of the latter have now been described. Of these a considerable number, especially those of earlier date, have to be excluded for our present purpose, since the tests applied to the isolated bacilli were not sufficiently stringent But even if we thus eliminate the cases of Vaillard,[8] Karlinski,[9] Vincent,[10] Beatty,[11] Pick,[12] Ohiari and Kraus,[13] we are still left with others, which are almost certainly representatives of this group, such as, for example, those described by Du Cazal,[14] by Dr. Cheadle,[15] by Dr. Bryant,[16] by Flexner and Harris,[17] and finally by Lartigau.[18] In these cases the patients, after having suffered during life from a disease resembling typhoid fever, presented no intestinal lesions post mortem, but the typhoid bacillus was recovered from many of their organs and often from the blood of the heart as well. *It is true that in none of* these cases was the reaction of the isolated bacillus to high dilutions of typhoid serum investigated. Dilutions of 1 in 20, of 1 in 50, and of 1 in 100 have been made by different observers, but not higher, and a possible source of error has thereby been introduced. Still, remembering that we are not dealing with a single case but with a series of cases all of which present more or less similar characters, remembering, too, that during life these patients have often presented the typical symptoms of typhoid fever, including the presence of rose spots, and bearing in mind that some at least of them have evidently been exposed to typhoid infection, other members of the family being ill with typhoid fever at the same time, there cannot be any moral doubt that the bacilli found were in truth the typhoid bacilli and that this variety of typhoid fever does really exist That it is uncommon is proved by the fact that at St. Bartholomew's Hospital no case has occurred during the last three years, though Widal examinations have been made in all suspicious cases as a matter of routine, and therefore such a case if it had occurred could not have been overlooked.

It is interesting to speculate on the entry of the bacillus in these cases. In this connexion an important fact strikes one on reading the records of the post mortem examinations It is that, though in all cases the intestine is described as being quite natural, yet in nearly all we find that the mesenteric glands were affected, being for the most part enlarged, swollen, and reddened, very much indeed as we find them in ordinary cases of typhoid fever. This would seem to suggest strongly that in these cases also the bacilli commonly enter the body through the intestine, passing, however, directly through the intestinal wall into the lymphatic glands, where they germinate and whence they become generalised as usual The passage of microorganisms such as bacillus coli through an apparently healthy intestinal wall is by no means uncommon There is no reason, therefore, to doubt that a similar passage might be sometimes effected by the typhoid bacillus

There would seem, then, to be the strongest evidence in favour of the view that sometimes, though rarely, the typhoid bacillus may pass into the blood and become generalised in the organs, just as occurs in ordinary typhoid fever, but without first causing any intestinal disease, even though, as is probable, the bacilli enter through the intestinal tract.

TYPHOID FEVER IN THE FŒTUS

In connexion with this class of cases it is interesting to notice that a very similar form of the disease is by no means uncommon in the fœtus. Indeed, fœtal typhoid fever of the primary septicæmic type is a frequent, though by no means the only, cause of the abortion which so commonly occurs during the disease. Experimentally it was shown many years ago by Chantemesse and Widal[19] that the placenta formed no bar to the typhoid bacillus, and at the present time a considerable number of cases are on record in which the micro organism has been found in the human fœtus. One of the most interesting of these is the following, observed by Dr. Andrewes, in the case of a fœtus from a woman suffering from typhoid fever, who aborted in the fourth month during the epidemic at King's Lynn. The typhoid bacillus in this instance was found in pure culture in the heart's blood and also in the spleen. Morphologically (including flagella) and culturally in all respects it resembled the typhoid bacillus while its agglutinable qualities were so marked that for a time it was used as the laboratory standard culture.

It should be noted, too, that in these cases, though the bacillus may be found in the blood and in many of the internal organs, the intestine is always natural (Etienne,[20] Freund and Lévy,[21] and Janiszewski[22]), and this indeed is what we might expect, seeing that the bacilli having broken through the placental barrier pass directly into the circulating blood without coming first in contact with the alimentary canal Typhoid fever, then, in the fœtus is an example of a primary typhoid septicæmia.

LOCAL TYPHOID INFECTION.

We have seen, then, firstly that ordinary typhoid fever consists in a primary intestinal lesion followed by a secondary generalisation of the bacilli, and, secondly, that cases may occur, very similar, clinically, in which the septicæmia is present but in which the primary focus of disease is wanting. We may now ask ourselves whether it is possible for the typhoid bacillus to produce merely a local disease without there being any symptom of general infection at all. Analogy would lead us to believe that this might be possible. Thus the pneumococcus is the specific cause of acute pneumonia, but sometimes it may produce a fatal septicæmia, and, again, in other cases it may give rise to merely a local disease such as an otitis media. As regards the first two lesions, therefore, it presents an almost exact parallel with the typhoid bacillus, and we have now to ask whether the parallel may not be drawn yet closer by an agreement on the third point. Experimentally in the lower animals there is no doubt that this is the case Thus it has been shown by Dmochowski and Janowski[23] that in dogs and guinea-pigs, if a subcutaneous injection of typhoid bacilli be made under certain conditions no general disease follows but merely a localised abscess We might, therefore, expect that occasionally in man a similar result might occur if from any cause the general resistance of the organism to the typhoid bacillus be increased. Two cases at least of this kind have been described and probably a third, two being examples of cholecystitis and one of cystitis. The first case to which I may refer is that of Dr. Cushing[24] The patient was a woman, aged 26 years, who, with the exception of an attack of pneumonia 10 years before, had never had any illness whatever, the history being perfectly clear on this point. She was admitted into the hospital with pain in the right hypochondrium which had attacked her five days before and had continued since Her temperature was 101° F., but it fell the next day to normal and remained down. The total duration of the fever therefore could not have been more than seven days at the most. The pain soon left her and a tumour, which proved to be the enlarged gall-bladder, was then felt. A fortnight later, the patient continuing well, abdominal section was performed and the gall-bladder was found enlarged, inflamed, and containing 15 stones The typhoid bacillus was found in pure culture in the contents of the gall-bladder. The patient made a rapid recovery. Here then we have a case of typhoidal cholelithiasis and cholecystitis, but without any evidence of typhoid fever, such as we understand it, having occurred at any time.

The case recorded by Dr. T. Houston[25] is also very similar.

In this case the patient had suffered for three years from symptoms of cystitis. The trouble began soon after she had been nursing a child who had died from "diarrhœa," but she herself had never had at any time any illness to suggest typhoid fever. After the symptoms had lasted for three years a bacteriological examination of the urine was made. It was found to be acid, to contain some pus and typhoid bacilli in pure culture.

In the third case, one of cholecystitis, recorded by Hunner,[28] the patient's symptoms, mostly attacks of severe pain in the right hypochondrium, had lasted on and off for some three and a half years. Operation was at last perform and the gall-bladder was found to be greatly distended and contain pus. Typhoid bacilli were obtained in pure cult from the latter. In this case, however, the patient had what she described as "remittent fever" 18 years befo so that it is conceivable that we are here dealing with case of prolonged retention of typhoid bacilli within body and not a local infection. The evidence, howev *seems to point to the latter.*

These cases, then, lend support to the view that typhoid bacillus is capable of causing sometimes merel

TABLE V.—SHOWING THE RELATIVE FREQUENCY OF THE VARIOUS COMPLICATIONS OF TYPHOID FEVER AS T OCCURRED IN THE FATAL CASES EXAMINED AT ST. BARTHOLOMEW'S HOSPITAL DURING THE PAST 30 YEARS.

Note.—Every complication which was observed has been classified in the Table. Any unusual complication not mentioned may therefore be regarded as not having occurred in this series of cases.

---

[28] Johns Hopkins Hospital Bulletin, August and September, 1899.

local disease, and it is probable that with the increasing number of careful bacteriological examinations now being made similar cases will soon be described.

COMPLICATIONS OF TYPHOID FEVER.

We may now pass from typhoid fever itself to a consideration of the complications and sequelæ which occur so frequently in connexion with it and which form so important a part of the disease. In considering them it was impossible not to be struck with the fact that we have no very comprehensive data concerning their frequency in England, none, at all events, comparable to those collected by foreign observers, and since there is no doubt that in different countries the relative frequency of various complications differs much it seemed that it would be of interest to analyse the results of the post mortem examinations in cases of typhoid fever which have occurred at St Bartholomew's Hospital during the past 30 years. The results are given in Table V. In all 300 post mortem examinations have been analysed, but, all the viscera not having been examined in each case, the percentages often depend on a smaller number. This, however, is noted in the table.

If, now, these results be compared with those of other observers as, for example, with the elaborate statistics obtained by Hölscher[27] from the Munich records, it will at once be seen that whilst some of the figures agree well together others show the most extraordinary differences. Thus, to name a few, while broncho pneumonia, empyema, and meningitis seem to occur as frequently in London as in Munich in connexion with typhoid fever, ulceration of the larynx is nearly five times more frequent in London, while perforation occurs in 30 6 per cent of our cases as compared with only 5 7 per cent in Munich. In London, that is to say, nearly one out of every three fatal cases is due to perforation, in Munich only one in 17—a truly extraordinary difference. On what exactly these great variations depend it is difficult in all cases to say, but the figures obtained at any rate clearly show the danger of believing that foreign statistics may represent even approximately the condition of affairs at home.

In considering the complications of typhoid fever one is naturally tempted to try to divide them into two great groups according as they are truly typhoidal—produced, that is to say, by the typhoid bacillus—or merely the result of a secondary infection by the pyogenic cocci. This, however, is impracticable, for, as we shall see, it is not uncommon for a given complication to be in one case homologous and in another heterologous in nature. Nevertheless certain complications are especially associated with the typhoid bacillus, and to a consideration of them I now propose to turn.

NERVOUS SYSTEM.

Meningitis.—Two complications referable to the nervous system may occur in typhoid fever, meningitis and neuritis. Both agree in being uncommon, both, too, in being truly typhoidal. The rarity of meningitis is well shown by the fact that it only occurred once in 117 cases at St Bartholomew's Hospital, the Munich records also in this case giving a very similar percentage. From the literature Keen[28] has collected 15 cases in which a bacteriological examination was made, and in all of them the typhoid bacillus was described as being present in the meninges and the meningeal exudation and in a considerable proportion in pure culture. Some of the cases doubtless are open to criticism, but the later ones and especially one by Ohlmacher,[29] have been carefully worked out and may be accepted. Meningitis, then occurring in typhoid fever, unless it be secondary to otitis media, should for the most part be regarded as directly caused by the typhoid bacillus, and to typhoid fever so complicated the term "meningo typhoid" may be justly applied. It should be noticed, also that in these cases the usual clinical symptoms of meningitis, strabismus and opisthotonos, are not as a rule present, but simply delirium or profound unconsciousness and coma. It is probable, too, that if the meninges were examined more frequently, especially in cases with severe nervous symptoms, the typhoid bacillus would be found not infrequently in this situation even in the absence of definite meningitis.

Neuritis.—The pathology of neuritis occurring after typhoid fever was not at first so clear. Thus it had been found by Dr. Sidney Martin[30] impossible to produce an artificial neuritis in animals by the injection of typhoid toxines, even though these were powerful enough to give rise to fatty degeneration of the heart and to kill the animals. It was conceivable, therefore, that it might be due to some secondary infection. Recently, however, Nicholls[31] in a very careful paper has shown in the case of the rabbit, that if the bacilli themselves be injected and the dose of poison thereby be greatly increased, then neuritis follows. Experimentally, then, the typhoid poison is capable of producing neuritis, and there seems no reason to doubt that when this complication occurs in man it is in general due to a similar cause.

RESPIRATORY SYSTEM.

The complications affecting the respiratory system in typhoid fever are numerous. Among the most important we may class ulceration of the larynx, bronchitis, and pneumonia, both lobar and lobular. Of these, bronchitis and broncho pneumonia need not detain us long, for though of very great importance clinically their pathology seems clear. They are examples of a secondary infection and are produced by the rapid growth under the influence of the fever of the pneumococci, streptococci, and staphylococci, normally present in the respiratory tract.[32]

Ulceration of the larynx.—Ulceration of the larynx, however, deserves a more special mention, both on account of its frequency (it occurred in 25 per cent of our post mortem examinations) and also because the condition was for long regarded as a specific part of the disease, the ulcers being looked upon as directly caused by the typhoid bacillus, in exactly the same way as are the ulcers of the intestine. The observations, however, upon which this view depended were made at a time when the widespread distribution of bacillus *coli communis* was unsuspected, and therefore cannot be relied upon. Moreover, the late Professor Kanthack and Dr Drysdale[33] in their interesting paper on this subject, showed how unlikely such a view was and how much more probable it was that the laryngeal ulcers were due to secondary infection, the tissues being predisposed by the disease itself. The accuracy of this view also has been strongly supported by the fact that since their paper was written no recent observer has discovered the typhoid bacillus in the ulcerations, though bacillus coli, streptococci, and other micro organisms have been found. There is little doubt, then, that the complication is not really specific but due to the pyogenic micro organisms.

Lobar pneumonia.—We may now consider the pathology of lobar pneumonia occurring in typhoid fever, a complication probably rather more frequent than is generally supposed, it having occurred in nearly 5 per cent of our fatal cases. It has been argued by some that, in certain cases at least, this complication is directly produced by the typhoid bacillus, while others hold that in all cases the pneumococcus is responsible for it, whether the pneumonia occur quite at the commencement of the typhoid fever or during its course. The matter is not a very easy one to settle finally. In the first place, it must be allowed that the typhoid bacillus may be found sometimes in the lungs even in large numbers, just as it may be found in other organs. Thus in a recent case in which infarction of the lung had occurred I obtained a pure culture of the bacillus from the infarct itself, the heart's blood, however, being sterile. There would therefore be nothing improbable in finding the specific bacilli in the consolidated lung, though this alone, of course, would not prove that they stood in causal relation with the pneumonia. In the second place, it is beyond question that in a great majority of the cases the pneumococcus is found in the lung, either alone or more rarely associated with the typhoid bacillus. This is generally admitted, and as an example it may be added that in two cases which have occurred recently at St Bartholomew's Hospital the pneumococcus was on each occasion present, the typhoid bacillus not being found in the lung. Whenever, then, the pneumococcus is present we must attribute to it without hesitation the pneumonia, and must assume that the typhoid bacillus is present only in a secondary capacity, just as it may occur sometimes in an infarct or in a fairly normal lung. As a result, then, we must allow that without doubt the great majority of typhoid pneumonias are due to the action of the pneumococcus. A few cases, however, are on record in which the typhoid bacillus has been found in culture but in which the pneumococcus has not been obtained, in one case at least, even after the inoculation of a mouse, the most certain test for the presence of the organism. It has, therefore, been hastily assumed that in these cases at all events we have to do with true typhoidal pneumonia. If, however, these cases be carefully investigated it will be seen that, as Karlinski originally pointed out, those cases in which the pneumococcus was not found were only examined quite late in the disease, at a time when commonly this micro-organism has already disappeared. In the very interesting case recorded by Bensaude,[34] for example, in which the patient had all the symptoms and physical signs of an initial pneumonia passing directly into typhoid fever, the exploratory puncture of the lung was only made on the tenth day. The fact, therefore, that only the typhoid bacillus could be grown from the exudation withdrawn while the pneumococcus could not be found, has but little weight. Similarly in the case recorded by Flexner and Harris[35] the patient had been ill for about two months, and from the history it would seem probable that the pneumonia started about two weeks before death. The absence here again of the pneumococcus has but little significance. At the present moment, then, we may say that no evidence exists to show that true lobar pneumonia is ever the result of the action of the typhoid bacillus. The future may conceivably reveal such cases, but before we can accept them two things are necessary: the bacteriological examination must be made early in the disease and several cultures from various parts of the diseased lung must be made. The absence of the pneumococcus, in fact, must be clearly demonstrated, not merely taken for granted as it were. If, then, the term "pneumo-typhoide," so commonly used by French writers, be retained, it must be understood that reference is merely made to cases of typhoid fever complicated by pneumonia, and that the term does not imply that the pneumonia is typhoidal. Probably, therefore, at present it would be wiser not to use the term. Similarly with regard to the term "pleuro-typhoide." A few old observations are on record in which apparently the first sign of the typhoid fever was a pleural effusion, and in one case Valentini,[36] and in a second Fernet and Girode,[37] isolated, as they thought, the typhoid bacillus in pure culture. Recent observations, however, have not confirmed this discovery, so that if the term be retained it must be merely as a clinical expression and must not at present be taken to imply a localisation of the typhoid bacillus in the pleura.

CARDIO-VASCULAR SYSTEM.

With the exception of phlebitis the complications referable to the heart and blood-vessels in typhoid fever are very rare, and even phlebitis in fatal cases is most uncommon. Thus in the last 30 years at St Bartholomew's Hospital only four cases with endocarditis have come to necropsy, two with pericarditis, and one with phlebitis. The cases in which arteritis leading to gangrene has occurred have all ended in recovery. As yet the pathology of these affections is somewhat obscure.

Endocarditis.—It may be said, however, that the endocarditis is generally of the malignant type and that it is the result of a secondary infection. This, however, is not so always, for the typhoid bacillus has been found in the warty vegetations. In one case observed by the late Professor Kanthack it was so found, not however in this case alone, but in conjunction with the pyogenic cocci.

Arteritis.—Of arteritis, the common cause of that dreaded though fortunately very rare complication, spontaneous gangrene, it is difficult to speak with certainty, owing to the extreme difficulty in obtaining material. In a recent case of typhoidal meningitis, however, described by Ohlmacher,[38] produced by the presence of the typhoid bacillus, marked acute endarteritis of the meningeal vessels was found. It is, therefore, probable that when the affection attacks the peripheral vessels it may have a similar pathology and may be due directly to the specific micro-organisms, or their toxines, and not to any secondary infection. It is likely, too, that if the state of the peripheral vessels were more carefully and frequently examined a mild degree of the condition would not uncommonly be found.

Phlebitis.—With regard to phlebitis a considerable number of recent observations have been made (Vincent[39]) and in many of the cases streptococci and staphylococci have been found in the clot and vessel walls, suggesting that the inflammation is really septic in nature, though probably produced by micro-organisms with but a low degree of virulence.

URINARY SYSTEM.

Nephritis.—The exact relation which the typhoid bacillus bears to the nephritis which in varying degrees of severity occurs so commonly in typhoid fever is hard to decide. It is certainly true that the typhoid bacillus may be present in the kidney after death in cases which show some evidence of nephritis, but lesions similar or even more severe frequently occur in cases in which the kidneys are sterile and in which therefore nephritis is evidently due to the excretion of toxic substances produced either by the typhoid bacillus alone or combined with those of other micro-organisms in cases where a secondary infection has occurred. Melchior[40] thus in his monograph records three cases of nephritis in which casts were found in the urine but in which in two cases the urine was sterile during life, showing that the kidneys could not have harboured the bacillus, while in the third case, which ended fatally, cultures proved the absence of the bacillus in the kidneys after death. The conclusion at which we may arrive, then, is that nephritis in typhoid fever is no proof of the presence of the bacillus in the kidneys. The toxines of the typhoid bacillus alone (or in combination with those of other micro-organisms) are quite sufficient to account for the majority of cases of nephritis which occur in typhoid fever. In some cases, however, in addition the bacillus may be present in the kidneys and will tend therefore to aggravate the condition.

Nephritis directly produced by the typhoid bacillus.—Very occasionally, indeed, cases of typhoid fever do occur, complicated by marked nephritis, in which it seems that the inflammation is directly produced by the local growth of the bacillus. The best known case of the kind is that reported by Thue[41] as early as 1889, in which on the thirteenth day the patient was found to be suffering from hæmorrhagic nephritis and in which post mortem the typhoid bacillus, as it was believed, was found in pure culture in the spleen and kidneys. The date of this observation, however, forbids us to place implicit confidence in it. Recently, however, a somewhat similar case has occurred at St. Bartholomew's Hospital. The patient, a man aged 22 years, who was under the care of Dr. Hensley, was taken ill on Dec. 21st, 1899, with pain and difficulty in micturition. He, however, continued his work until Dec. 30th, the ninth day of his illness. On Jan. 1st, 1900, he was admitted and was found to be suffering from typhoid fever (spots being present and the Widal reaction positive) and also nephritis. The urine contained blood, *very many casts*, a good deal of pus, and one-tenth of albumin. On Jan. 3rd (the thirteenth day) it was examined bacteriologically and was found to contain a pure cultivation of typhoid bacilli. The patient had a severe attack of fever, complicated by laryngitis. The temperature reached normal on the thirty-fourth day. The nephritis continued throughout the illness and the bacilli still persisted in the urine in undiminished numbers. (For exact details concerning the date and number of the observations made on the urine compare Table VI., Case 17*a*, and Appendix, Case X.) On the thirty-fifth day, the day after the temperature had reached normal, the urine under the administration of urotropin was freed from bacilli and the thick deposit of pus which had hitherto been present (typhoidal cystitis). After a few days, also, the casts became less and with the albumin gradually disappeared. It would seem, then, that in this case the nephritis stood in direct relation to the typhoid bacilli, for, apart from the striking effect of treatment, the improvement in the condition, dating almost directly from the elimination of the bacilli, it seems difficult to ascribe so marked a nephritis observed on the eleventh day, and undoubtedly present earlier, to toxines only. Moreover, the bacilli were evidently present in the urine and kidneys from a very early period of the disease. They were cultivated first on the thirteenth day, but the first symptom which drew the patient's attention to his condition was some pain and difficulty in micturition, due doubtless to typhoidal cystitis, and evidencing the presence of the micro-organisms even at this earlier stage. For these reasons, then, we must regard the case as one of true typhoidal nephritis, or in its truest sense one of "nephro-typhoid." The extremely early date at which the generalisation of the bacilli must have occurred is of great interest.

TYPHOID BACILLURIA AND CYSTITIS.

I may now pass to the bladder and the urine in typhoid fever. In drawing attention to the presence of the bacilli in the urine some little time ago[42] I was only able to prove without doubt the existence of the condition and could not venture at that time to state how frequent its occurrence might be. Lately, however, I have had the opportunity of examining a larger series of cases and the results of my observations I now bring forward. They are recorded in Table VI. It will be seen from it that in all 45 cases of typhoid fever have been investigated. In 28 of these, though examined on several occasions, the urine was never found to contain typhoid bacilli, while in 17 the bacilli were found. This would give apparently a percentage of nearly 38 for the positive results. It is, however, undoubtedly too high, for out of the 17 positive results six were cases in which the abnormal condition of the urine had attracted attention and in which a bacteriological examination was therefore requested. Eliminating these, then, we find that 39 typhoid fever cases have been taken at random in the wards and the urine examined on several occasions. Of these cases 28 never contained typhoid bacilli, while 11 contained them in large quantities, constituting a percentage of 28. In London, then, at all events it will probably be correct to say that at least 25 per cent. of all cases present this serious and dangerous condition. This conclusion is also supported by the fact that it agrees approximately with the results obtained by Richardson.[43] This observer, working in Boston, examined the urine in 102 cases of typhoid fever, and in 23 he was able to isolate the bacillus, obtaining therefore a percentage of 22.5. At the present time, then, the evidence would show that the condition is one frequently met with and that it probably occurs in one out of every four typhoid fever patients.

Naked-eye recognition of typhoid "bacteriuria."—An important point, also, in connexion with the condition is the fact that very commonly the bacilli are present in enormous numbers, so that the urine is rendered turbid. I was at first inclined to regard these cases as rare, but really they are the rule rather than the exception. Thus out of 14 recent cases in which this point was especially looked for, in 12 I found that the urine was turbid with bacilli, while in two only was it noted as "clear," and the microbes were accordingly first discovered on cultivation. The enormous numbers in which the micro-organisms may be present, though it increases the danger of the complication, brings with it the advantage that the condition can be recognised, or rather suspected, more easily. Indeed, this can often be effected by the naked eye. All that is necessary is to pour the turbid urine into a test tube and then holding it up to the light gently to shake it. If the turbidity be due to the presence of micro-organisms we notice at once a curious shimmer in the liquid exactly comparable to that seen in shaking any turbid broth culture, a phenomenon which is not seen when the urine is cloudy from other causes, such as phosphates, urates, &c., probably because the amorphous particles of which these deposits consist are unable to catch and reflect the light in the same way as the regularly shaped bodies of the bacteria. If, then, in a turbid typhoid urine this curious shimmer is seen it may at once be predicted that the urine is full of micro-organisms, and the typhoid bacillus should be at once suspected, for experience shows that when this condition is noticed in typhoid fever, *if the case be a male*, it is most commonly due to the presence of the true typhoid bacillus. This, however, can only be proved by cultivation, and even in the male the same naked-eye appearance may sometimes, though much less commonly, be produced by other microbes, such as the bacillus coli communis, the streptococcus pyogenes, and the staphylococcus aureus. In the female, however, much less reliance can be placed on a mere inspection of a naturally passed urine, the sources of contamination being too gross.

Conditions governing the appearance of the bacilli.—The conditions under which typhoid bacilluria occurs are subject to great variation. Thus, the bacilli may make their first appearance in the urine at any period of the disease, from the early days of the fever down to a time when convalescence is already established. The earliest date on which I have myself isolated them was the thirteenth day, and in this case they had undoubtedly been present from a much earlier period. The latest date, on the contrary, on which I have known them first to occur was the fourteenth day of convalescence. Speaking generally, however, we may say that the condition is rare before the third week of the disease. After this it may occur at any time during the fever, but not uncommonly its occurrence is delayed until the early days of convalescence. It is, therefore, much more closely associated with the later stages of the disease. The duration of the bacilluria also varies much, but it nearly always persists for some considerable time. The shortest duration recorded is eight days, but in four other cases it had not disappeared until after the lapse of 21 days, 25 days, 30 days, and 70 days. Occasionally it may persist, not for months, but for years, as in a remarkable case recorded by Gwyn.[44] In this case the patient had been in hospital five years before with an attack of typhoid fever. Ever since his discharge he had had trouble with his bladder, and on re-admission five years later he was found to be suffering from cystitis and the typhoid bacillus was obtained in pure culture from his urine.

Frequency of associated pyuria.—The condition of the urine, too, offers no constant qualities. Not uncommonly, even when millions of bacilli are present, albumin is totally absent, and when present it usually does not amount to more than a trace or a cloud. In rare cases it may be present in larger quantities—one-sixth or one-seventh in two of my cases. In one case hæmaturia occurred. Although, however, albuminuria is not conspicuous in these cases it is not at all uncommon to find pus, sometimes even in considerable quantities. Thus of my 17 cases nine, or over 50 per cent., showed pyuria. The urine in nearly all cases was acid. It was never ammoniacal.

Lastly, it has sometimes been said that the cases in which typhoid bacilluria occurs are more severe clinically than those not showing this condition. Taken as a whole this is true, but it is equally true that patients may have typhoid fever of extreme severity without the urine ever becoming infected. In no case, then, we can say from the condition of the patient or from the presence or absence of albuminuria that bacilluria has occurred. We should, however, suspect it if either the urine becomes suddenly turbid and manifests the "shimmer" appearance or if pyuria occurs.

THE PATHOLOGY OF THE CONDITION.

A few words may now be devoted to the pathology of this condition. How is the bacilluria produced and on what does it depend? The simplest explanation which suggests itself—namely, that we have to do with a mere filtration of the bacilli from the blood—may be at once dismissed. The extreme difficulty in finding the bacilli in the blood during life, to which I have already referred, would point to its improbability. Moreover, I have on four occasions examined the blood bacteriologically, at a time when the urine was swarming with bacilli, and on all occasions I failed to find the typhoid bacilli therein. Evidently we are not dealing with a mere filtration. A second possibility is that the condition arises from suppuration set up in the kidney by the typhoid bacillus, accompanied by the secondary passage of the bacilli and pus into the urine. Such cases of suppuration do undoubtedly occur, one being recently recorded by Flexner,[45] but they are extremely rare. Thus out of 289 typhoid post-mortem examinations at St. Bartholomew's Hospital in one case only were abscesses found in the kidneys. This rare condition, therefore, could hardly explain the very frequent presence of the bacilluria.

We are driven, then, to our third possibility to offer an adequate explanation of the condition. According to this view, which I believe to be correct, the whole would depend on the rapid growth of the bacillus in the urine itself within he bladder, a stray micro-organism having found its way there from the blood, doubtless after its passage through the kidney. This explanation would seem to meet the facts of the case, for it would explain the chief peculiarities of the condition—viz., the sudden onset of the affection, the enormous numbers of the micro-organisms, and not uncommonly the total absence of albuminuria. It would also readily explain the frequency of pyuria in these cases, which would be thus due to the onset of cystitis. It has, however, by some observers been doubted whether the typhoid bacillus can grow and multiply in urine. As a matter of fact, there is no doubt that it is able to do so. Thus I found that out of six samples of urine taken and inoculated with the typhoid bacillus and then incubated at 37° C. four showed general turbidity, though varying in degree, from growth of the micro-organism at the end of 18 hours, while two did not. These latter, however, showed good growth at the end of 48 hours. The typhoid bacillus evidently, then, can grow in most urines, though the rapidity of growth varies with the specimen of the urine used. On the latter fact also doubtless in part depends the absence of the bacilli in the urine in so many cases of typhoid fever. We must believe that in every case, since the bacilli always pass into the blood, every now and then a stray bacillus is carried into the kidney and so passes into the urine. If, however, the urine be in this case not very suitable to the growth of the micro-organism, and if, too, the bladder be evacuated frequently and completely, then no harm will result, for the micro-organism will be excreted in the urine before it has time to multiply. If, however, as is often the case in typhoid fever, the patient only passes his urine at long intervals, perhaps not emptying the bladder completely, then if the urine be a favourable medium the bacillus will have ample opportunities to grow and multiply, and marked infection of the urine will result.

[45] Journal of Pathology and Bacteriology, 1898, vol. ii.

In addition, however, to the above considerations we have positive evidence that the *fons et origo* of the condition lies in the bladder itself. In the first place, the condition can be cured by local treatment—viz., the injection of antiseptics into the bladder. This was shown very clearly by Richardson[46] who in a given case, having failed with boric acid, was at once successful when perchloride of mercury (1 in 7000) was substituted. Gwyn[47] also has had a similar experience. Secondly, a short time ago I had the opportunity of examining one of these cases post mortem. The

[47] Loc. cit., vide note 44.

patient was a man, aged 31 years, who died on the nineteenth day of the disease from heart failure The urine was examined a few hours before death and was found to contain one seventh of albumin and to be strongly turbid with typhoid bacilli in pure culture Death occurred a few hours later At the post mortem examination the usual intestinal lesions of typhoid fever were found. The Peyer's patches and solitary follicles were swollen and beginning to ulcerate. The spleen was enlarged and soft The kidneys to the naked eye showed only engorgement and microscopically nothing beyond "cloudy swelling" could be demonstrated. The bladder, however, showed a few scattered hæmorrhages and its mucous membrane was slightly injected Bacteriologically the typhoid bacilli were demonstrated by culture in the spleen, the liver, and the gall bladder, as well as the bladder urine, but the cultures from the heart's blood, the lungs and both kidneys were sterile I should say that four separate bacteriological examinations were made from the kidneys, two from each organ, but all four yielded absolutely negative results In this perfectly typical case, then, there can be no doubt as to the source of the bacilli They were not found in the blood or in the kidneys, but they were present in the urine in enormous numbers There would seem therefore to be no reasonable doubt that a stray bacillus had passed into the urine and had multiplied there and so given rise to the condition

(R) signifies that the observation was made during a relapse

If, then, this proves to be, as I believe, the true pathology of the affection we are evidently dealing with what may be called a specific "bacteriuria," meaning by this term that the urine is swarming with micro organisms, though no definite symptoms are produced by this condition This affection has been known for years Indeed, it was the late Sir William Roberts[43] who first drew attention to it. His observations, however, did not attract general notice and it was not until 1894 that Krogius[44] again brought the matter forward In the *Annales Génito Urinaires* for that year he published eight cases of this condition all due to the presence of bacillus coli communis, and since this date other writers have confirmed his observations Indeed, the condition is almost certainly more common than is generally imagined.

It is, however, recognised by those who have worked at this subject that no hard and fast line can be drawn between bacteriuria and cystitis That is to say, that while a typical case of bacteriuria will give rise to no symptoms and will at most show under the microscope a few scattered pus cells in addition to the bacilli, there are others in which the patient may complain of slight pain in passing the urine and slight frequency of micturition, the number of leucocytes also increasing, but still not forming a deposit visible to the naked eye Finally, these cases merge again into cases of frank cystitis Now this is exactly what is also noticed in the bacilluria of typhoid fever According to my experience about half the cases are examples of simple bacteriuria. The patients complain of absolutely no symptoms whatever; there is no frequency of micturition and no pain accompanies the act. The urine itself swarms with bacilli and beyond this nothing can be seen abnormal in it. Under the microscope, however, an occasional pus cell can generally be found. These cases are nearly always undetected because of the absence of symptoms. There are, however, others in which, in addition to the bacilli, there is an evident deposit of pus visible to the naked eye, showing that the bladder mucous membrane has become slightly inflamed. The inflammation, however, must be very slight, for usually in these also no symptoms are manifested. Lastly, we have cases in which, while the urine remains the same—that is to say, contains bacilli and pus, but remaining of course acid, since the typhoid bacillus has no power to decompose urea—we have clinical symptoms—namely, pain and frequency of micturition and possibly tenderness over the region of the bladder. These cases of obvious typhoidal cystitis are rare. No. 6*a*, Table VI. of my series (Appendix, Case II.) was, however, such a case, and other cases have been reported, for example, by Krogius[50] and a notable one by Melchior.[51] To this latter case I should like to draw special attention, for though published in 1897 in his monograph on cystitis it was observed in 1892, and is probably the first case of cystitis due to the typhoid bacillus ever diagnosed.

[43] Brit. Med. Jour., vol. ii., 1881, p. 353 and p. 623.
[44] Annales Genito-Urinaires, 1894, p. 19.

How are we to explain these differences—viz., that in some cases we have merely a bacilluria and in others a true cystitis? Evidently from our knowledge of the fact that the mere presence of bacteria in the bladder is not sufficient of itself to cause cystitis. Some predisposing cause is also necessary, as, for example, some injury to the bladder walls. Now, in typhoid fever so many tissues suffer from the effects of the fever that it is not a very hazardous assumption to believe that in some cases the mucous membrane of the bladder may be damaged with the rest.

If, then, in a case of typhoid fever the bladder mucous membrane is in a natural condition and if the urine be passed at the usual intervals, then if bacilluria occurs it will remain a simple bacilluria. But should there be marked retention or should the bladder walls have been damaged in any way during the course of the disease then we have the condition in which a frank cystitis may be set up.

It is interesting to note, too, that this view receives valuable support from experiment, which shows that according as the circumstances vary the typhoid bacillus is capable of causing now a simple bacilluria, now a pure cystitis. Thus, Melchior[52] showed that if a rabbit be taken and one cubic centimetre of a broth culture of typhoid bacilli be injected into the bladder no symptoms follow, but a bacilluria lasting for about ten days results. If, however, immediately after the injection the penis be ligatured for some hours and retention be produced then true cystitis follows. *There can be little doubt, then, from the above considerations that typhoid bacilluria, such as we see it in the wards, is due to infection of the urine by a stray typhoid bacillus, excreted by the kidneys from the blood, and its immediate multiplication in the bladder-urine. If in addition the bladder walls have been in any way damaged, then true typhoidal cystitis follows.*

Specific bacilluria and cystitis occur, as we have seen, not infrequently in typhoid fever. It would be a mistake, however, to suppose that in every case when "bacteriuria" occurs in this disease it is due to the typhoid bacillus As a rule, the typhoid bacillus is the microbe present, but in rare cases bacteriuria may be produced by the streptococcus pyogenes, or even by the staphylococcus aureus, facts demonstrated in the accompanying reproductions of photographs, which represent in each case a drop of the urine as passed dried on a cover-glass and stained. Similarly, though cystitis in typhoid fever, when not the result of catheterisation, is far most commonly set up by the typhoid bacillus, we must remember that other micro-organisms may produce it. Thus cases exactly similar to the typhoidal ones may result from the invasion of bacillus coli. Indeed, it is surprising that invasions by this and other micro-organisms are not more common when we remember the opportunities offered by the ulcerated intestines.

CHOLECYSTITIS.

It is interesting to note that a very close parallel may be drawn between the relation of the bacillus to the urinary bladder and that which it bears to the gall-bladder. In the latter, just as in the former, it is not uncommon for the micro-organisms to be present in large numbers, but to give rise to no symptoms. Should, however, retention be produced or the walls irritated by the presence of gall-stones then cholecystitis follows, just as cystitis does in the case of the urinary bladder. Ten such cases have been recorded by Hunner,[53] many of them occurring at some considerable time after the attack of typhoid fever, and in all the typhoid bacillus was found at the time of operation in pure culture. Moreover, the parallelism may be pressed further, for, just as cystitis in typhoid fever will sometimes depend on the presence of bacillus coli and not on that of the specific micro-organism, so also the same may occur in the case of the gall-bladder Thus five cases of post-typhoidal cholecystitis in which bacillus coli communis was found in pure culture in the inflamed organ are recorded in Cushing's[54] interesting paper.

TYPHOIDAL CHOLELITHIASIS.

In reading the record of the true typhoidal cases of cholecystitis it is noteworthy how almost constantly gall-stones were found at the time of operation. Indeed, so striking is this fact that it early led to the idea that the typhoid bacilli themselves were the cause of the cholelithiasis, and that, as a rule, it was only after the formation of the stones that the inflammation of the gall bladder took place—a view which would well agree with the fact that not uncommonly it may be months, or even years, after the original fever before the cholecystitis occurs. *The theory is supported by the fact* that, as Naunyn[55] and others have shown, micro organisms may often be found in the centre of recently formed stones, and also by the observation of Richardson[56] that not uncommonly after death the typhoid bacilli in the bile may be found agglutinated. He observed this in five out of six cases in which he examined the bile, and although these numbers give too high a percentage they certainly prove that the condition is no uncommon one. It is easy to see how this agglutination, when it occurs would form a nucleus round which biliary salts would be deposited and thus lead directly to the formation of stones. Recently the matter has been carried a stage further, for both Gilbert and Fournier[57] and also Richardson[58] have succeeded in producing artificial biliary calculi—the former in the rabbit by the injection into the gall bladder of attenuated typhoid cultures and the latter in the guinea pig by the use of already agglutinated bacilli. From the centre of Gilbert's calculus, also, typhoid bacilli in pure culture were obtained. There can be hardly any doubt, then, that the typhoid bacillus is capable of leading directly to the formation of gall stones, and it is easy to see how the latter would assist the former in setting up the cholecystitis. If, then, inflammation of the gall bladder occur after a case of typhoid fever, and the specific bacilli be found in pure culture, the sequence of events in all probability has been, first the formation of gall stones and only secondly cholecystitis. In a few cases—and this is especially seen in those rare ones occurring during the fever itself—the gall bladder may become inflamed primarily through the action of the typhoid bacillus, without gall stones being present. But in these cases just as with typhoidal cystitis, the walls have in all probability been damaged through the stress of the disease and the predisposing cause is therefore already present.

SUPPURATION IN TYPHOID FEVER

We may now turn our attention to suppuration in typhoid fever. In the earlier days of bacteriology all suppurations occurring in typhoid fever were regarded as due to a secondary infection by the pyogenic micro organisms, and the experiments of Dmochowski and Janowski[59] and others, showing that experimentally the typhoid bacillus itself is quite capable of producing suppuration, came therefore somewhat as a surprise. *Their correctness, however, was soon* demonstrated, for it was shown that not uncommonly in man the typhoid bacillus could be obtained from the pus in pure culture. These cases have lately been collected by Keen,[60] and they show clearly that in the most diverse situations *suppurations due to the typhoid bacillus have occurred.* It would be a grave error however, to suppose, as is sometimes done, that the majority of typhoid suppurations are directly due to the typhoid bacillus. This is certainly not the case; the greater number are without doubt the result of secondary infections and are produced by the ordinary micro-organisms of suppuration. This point was very clearly brought out by Vincent,[61] who in 1893 examined bacteriologically 41 cases. 32 of these cases were produced by the staphylococcus aureus or citreus, eight by the "streptococcus pyogenes either alone or in conjunction with the typhoid bacillus," and one only was produced directly by the typhoid bacillus alone. The great preponderance of cases due to the pyogenic cocci is thus well shown, and this is a point which we are apt to forget at a time when nearly every case due to the typhoid bacillus rapidly finds its way into print.

In suppuration, however, connected with bones, post-typhoidal periostitis and osteomyelitis, which Sir James Paget[62] was one of the first to describe, it is undoubtedly much more common to find the typhoid bacillus, and the reason of this is not far to seek when we remember how constant is the presence of the bacillus in the bone marrow during the disease. Keen[63] in a careful survey of the lately published cases finds that of 51 cases in which a bacteriological examination was made, 38 contained the typhoid bacillus and 13 the pyogenic micro organisms, while Parsons[64] in six cases found the typhoid bacillus in pure culture in four cases and associated with the staphylococcus citreus in one case; in only one case did he find the staphylococcus aureus alone. At St Bartholomew's Hospital the typhoid bacillus has not been found quite so *frequently*. Thus out of four cases of periostitis examined in two only was the typhoid bacillus found, once alone and once associated with the staphyloccus.

Speaking generally, however, it will be true to say that *while it is very common to find the typhoid bacillus in pure culture in the abscesses connected with bone, in suppurations occurring elsewhere its presence is undoubtedly rare.*

The following table from the records of St Bartholomew's Hospital, the observations having been made by the late Professor Kanthack, Dr Drysdale, or myself, demonstrates these points clearly and especially shows the rarity of the typhoid bacillus in inflammations unconnected with bone. In eight such cases examined it was not once found.

TABLE VII.—*Typhoid Suppurations.*

No.	Nature of the suppuration	Micro-organisms found	—
1	Periostitis, sternum	Typhoid bacillus (pure culture)	—
2	" " right tibia.	Typhoid bacilli + staphylococci	—
3	" " left tibia	"No typhoid bacilli"	Typhoid bacilli not present
4	Periostitis distal phalanx of the thumb	"Pyogenic cocci"	
5	Parotid bubo	Staphylococcus pyogenes aureus	
6	*Ischio-rectal abscess*	Bacillus coli and streptococci	
7	" "	Streptococci.	
8	Subcutaneous abscess	Staphylococcus pyogenes aureus and albus.	
9	"	Staphylococcus pyogenes aureus	
10	" "	Staphylococcus pyogenes aureus	
11	Subcutaneous and intra muscular	"Pyogenic cocci."	
12	Mammary abscess	Staphylococcus pyogenes aureus

THE PERSISTENCE OF THE TYPHOID BACILLUS IN THE BODY.

There is one other point which it may be of interest now to consider, and that is, what is the length of time during which the bacillus may remain in the body? It was naturally supposed at first that as the fever passed away and as health returned the bacillus, the cause of the disease, would disappear from the tissues also. This apparently was demonstrated by the earlier observations Thus it was shown long ago that if the spleen or mesenteric glands—the classical breeding grounds of the microbe—be examined late in the disease no typhoid bacilli are found, the organs being either sterile or possibly containing bacillus coli communis. This has been noticed by Flexner[65] as early as the sixth week, while Dr. Klein[66] has recorded it in the ninth week of the disease. The experiments of Blackstein and Welch,[67] however, showed that, sometimes at least, the typhoid bacillus might remain for much longer periods in the body. Thus after intravenous injections of the bacillus into rabbits they found that the bile still contained the micro-organism when the animals died or were killed at such long intervals as 84 days, 109 days, and even 128 days after the date of inoculation. The other organs were, however, found sterile.

These experimental results in animals naturally suggested that the same thing might occur in man after typhoid fever, and this has been amply demonstrated, for we now know that it is nothing uncommon for the bacilli to remain dormant in the bile or the bone marrow for long periods, the patient, just like the experimentally inoculated animal, being meanwhile often in perfect health, and then under the influence of some passing stimulus to resume their activity and to give rise now to periostitis, now to osteomyelitis, or it may be to cholecystitis. Of the later cases belonging to the former group (bone affections) the chief interest centres round those recorded by Buschke,[68] Sultan,[69] and Bruni,[70] in which the bacilli were found in pure culture in the pus in two cases six years after the primary fever and in one case seven years afterwards. By far the most important is that of Bruni, on account of the very great care exercised in testing the isolated bacillus, so that his case may be accepted without hesitation The patient was a woman, 36 years old, who suffered from typhoid fever in September, 1889. During convalescence she had some pain over the right tibia which lasted for some time, but which gradually disappeared. After some years, however, it returned and becoming worse she presented herself at the hospital in the year 1895 six years after her primary attack. The upper part of the right tibia was found to be swollen and reddened, and osteomyelitis was diagnosed. The bone was consequently trephined and in the centre a cavity filled with grumous pus was discovered. The contents contained the typhoid bacillus in pure culture. This case may be accepted without any doubt, and is only a type of many others recorded though not so rigorously examined. If we now turn to cholecystitis we find the same remarkable facts. Thus, to mention but a few, though many are recorded in Hunner's interesting paper.[71] In one case the bacilli were found in pure culture in the inflamed gall-bladder three months after the fever, in another eight months, and in a third after an interval of seven years. The most remarkable case of all, however, and one very carefully tested, is that recorded by Von Dungern[72] in which fourteen and a half years after the attack of typhoid fever the bacilli were still present in pure culture in the pus. Truly no longer can we say with Dr. Budd[73] that "by destroying the infectious power of the intestinal discharges the disease may be in time finally extinguished." So far, indeed, from the stools being the only agents by means of which the disease is spread they are but one of a series of agents So far, too, from the patient ceasing to be a source of danger after his restoration to seeming health he may carry about in himself the seeds of infection for months and even years.

THE TREATMENT OF RHEUMATISM, ITS PROPHYLAXIS AND CARDIAC COMPLICATIONS.[1]

By SIR RICHARD DOUGLAS POWELL, BART., M.D,
F R.C.P. LOND,
PHYSICIAN-IN ORDINARY TO THE QUEEN; PHYSICIAN TO THE MIDDLESEX HOSPITAL AND TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON

I MUST first of all acknowledge the great honour, which I feel it to be, to be requested to make some final remarks in conclusion of this discussion and I will mark my sense of that honour by being as brief as I can consistently with due respect to the number of very able and eminent speakers who have preceded me. I think, after hearing the remarks of some speakers at the last meeting and still more after the remarks of most speakers at this meeting, that we may fairly say that the profession are certainly prepared to accept, if not to welcome, the arrival of a microbe as representative of the rheumatic disease provided that it be duly accredited to us by scientific investigation. I am bound to say that although we have been well prepared for the possible advent in some saprophytic form of such an organism by the most elaborate and able Milroy Lectures of Dr. Newsholme to the Royal College of Physicians of London, the points of which have been given to us so carefully by Dr. W. Ewart, yet these arguments, meteorological, bacteriological, epidemical, or clinical, do not, I think, do more than lend colour to a preconceived hypothesis, however scientific it may be, of the possible existence of such a microbe. The position most likely occupied by such an organism has been placed near the surface of the soil. It is presumed to dwell in certain localities and even to lurk about certain houses; its avenues of entry have been defined as through the tonsil or possibly the air-passages or digestive tract, but beyond these statements with regard to the organism we cannot say that we know anything whatever about it and it has never been demonstrated to us It does not, however, follow that it may not appear, and that soon. We can have no quarrel with any hypothesis which leads to so practical a therapeutical suggestion as that initiated by Dr. T. J. Maclagan—viz., the introduction of the salicyl compounds in the treatment of rheumatic fever

There have been certain organisms discovered in rheumatic fever alluded to by Dr. Ewart—viz., the staphylococci, the streptococci, the pneumococci, and I think a few others—which have been found by certain observers more particularly in those cases in which the rheumatic fever has been associated with tonsillitis, and an interesting paper was read by Dr. P S Abraham before the Clinical Society last June in which he speaks of cases of rheumatic fever associated with throat affection. He divided these cases of rheumatic tonsillitis into two forms—faucial erythema, with which we meet as part of the rheumatic illness and tonsillitis proper, the latter including follicular tonsillitis and ordinary quinsy. Dr. Abraham found these organisms in the secretions and sections of the tonsils, in the blood, in the urine, and I think in the joint fluids. Dr. Abraham's observations are to my mind of great interest, but I venture to doubt whether they really throw much light on the point which he was trying to introduce—viz, the possible result of rheumatism from these causes. Dr. Abraham alluded to 11 cases, all of which were children except one, and from other facts mentioned in the paper I gather that almost all his throat cases were cases of follicular tonsillitis. I am not surprised at these organisms being found in the follicles of the tonsils and in the blood in the case of follicular tonsillitis, for follicular tonsillitis is a disease which is always regarded as one suggestive of at least a mixed infection, and one never sees a case without careful inquiry as to drains and sanitation. It was interesting to me to remember the occasional occurrence—I have only met with two cases—of infective endocarditis as a process arising in the course of primary acute rheumatism, and the fact of finding such organisms in association with acute rheumatism would lead one to see how perilously possible the occurrence of infective endocarditis may be in such cases.

---

[1] The reply to the debate on the Treatment of Rheumatism at the Chelsea Clinical Society delivered on March 20th, 1900

With regard to the blood, however, but little has been said. There is a characteristic sign and a diagnostic sign almost, one might say, of a remarkable increase of fibrin in rheumatic patients only equalled by that found in pneumonia; the red corpuscles are notably decreased and the white corpuscles are increased. The total acidity of the blood is increased, or it is better, perhaps, stated that the total alkalinity of the blood is diminished. This acidity of the blood led many years ago to the lactic acid hypothesis of rheumatic fever which, I think, has been trenchantly criticised by Dr. Pye-Smith as an exploded idea. Whether this increased acidity be the result of some modified local metabolism or of some disordered intestinal secretion leading to the production of some ferment or to the advent of the bacterial ferment, which has been so largely supposed in the present discussion and in the current literature of the day, I am quite unable to say. On these points we must wait with due reserve for the further researches which are sure to be made and the enlightenment which will surely come to us.

It is a curious fact that the nervous system has been almost entirely forgotten in the present discussion and yet some will remember how lively a discussion took place 25 years ago as to the origin of rheumatic fever as a neuropathy, in which Dr. T. Buzzard took a very prominent part. When one considers how very closely allied the nervous system and arthritis are one cannot be surprised at such a hypothesis having arisen We know perfectly well that rheumatic arthritis is almost invariably a disease preceded by some appreciable nervous shock, agitation, or prolonged anxiety, and Charcot's neuro-arthritic cases are well known. Hyperpyrexia in rheumatic fever is almost the only possible way of people dying in this disease except from direct cardiac lesions. Hyperpyrexia is a paralysis of the thermic control centres and is closely associated with the recedence of the proper rheumatic manifestations, although it is found in other diseases as well. Again, chorea is a disease of rheumatic and of nervous manifestation, and I must say that it was ingeniously and attractively disposed of by Dr. A. E. Garrod by saying that it was a sequel of rheumatic fever just as diphtheritic paralysis and such nerve-lesions may be sequelæ of diphtheria arising from the specific action of toxins on the nerve centres.

With regard to the prophylaxis of the disease I do not think anything is to be said. Dr. Ewart asked many questions about the prophylaxis of rheumatic fever and he proposed to us a good many conundrums, but he did not answer them so far as I know. If one may criticise Dr. Ewart's paper in a kindly spirit I should agree with Dr. A. E. Sansom's remark that it was a little too arthritic Arthritis is an essential feature of rheumatism even in children. You rarely meet with a child with "cardiac rheumatism" who has not exhibited pains called by the friends "growing pains" sufficient to hamper the liveliness of the child. The peculiar arthritis in acute rheumatism is a part of the disease, it is as ephemeral as the rose-spot of typhoid fever, with which to my mind it is closely analogous, and the duration in each joint is about the same. When it lasts longer in one or more joints one finds that the disease is not a pure disease but a mixed disease, such as gonorrhœal rheumatism or a rheumatism in association with hæmophilia, or possibly complicated by tubercle.

Still greater difficulty have I in regarding rheumatism exclusively from the cardiac side. Dr. D. B Lees says it is a cardiac disease with arthritic complications. Dr. Lees deserves our gratitude for the clearness with which he puts before us any hypothesis he may have. There is no doubt whatever as to what he means; he briefly and frankly states the whole case from his point of view. With regard to cardiac dilatation in rheumatism, he regards cardiac disease not necessarily as endocarditis, but as a gradual affection leading to the dilatation of the organ, and I think it is an interesting thesis for discussion. I confess that I had not observed this dilatation of the heart as a constant effect in rheumatism. It is possible that I have overlooked it. One examines patients, but looking back no one can say that he has examined all the cases with sufficient accuracy with regard to this one point to be able to exclude it. In anæmic cases, and especially in anæmic young women, who so commonly come into hospital with rheumatic fever, one frequently, of course, observes some cardiac dilatation. One may meet with cardiac dilatation in any febrile condition, and one is accustomed to regard it as attributable to that condition of muscle present in association with high temperatures to which pathologists give the delightful term of "cloudy swelling." I do not know quite what it means, but it is attended with a somewhat less distinct outline of the elements of the muscle and an increased softness of the tissues and is a condition that is very compatible with the possible yielding of the muscle before the blood pressure. Myocarditis we meet with as a cause of the enlargement of the heart, and fatty degeneration is a rare cause of sudden death in rheumatism. But these facts will not at all explain Dr. Lees's findings with regard to the heart in acute rheumatism; there is, so far as I can gather, scarcely any way out but that the heart must be partially paralysed by some definite poison affecting it, such a poison as Dr. Lees describes as an undue acidity of muscular texture. Then, again, the rapid diminution in the enlargement of the heart under treatment is another point observed by Dr. Lees. Dr. Ewart at a meeting of the Clinical Society of London endeavoured to explain these cases by saying that there was some temporary effusion into the pericardium, but Dr. Lees will not admit this; and I can conceive no explanation except that which Dr. Lees expounded, only I think that he would fully expect that his observations would be received with a respectful scrutiny on the part of those to whom it was first presented. As regards the description, the definition of rheumatism, I should much prefer the very accurate definition which was given us by Dr. Archibald Garrod that it is "a systemic disease with arthritic and cardiac manifestations," a definition which is accurate and which is safely within the limits of our knowledge of the actual causes at work in acute rheumatism.

In my second Lumleian Lecture two years ago I ventured to sum up in a sentence the current treatment of acute rheumatism, which has drifted down to us from the experience of many years past. Such patients should be treated by "absolute rest in bed in woollen wrappings, a free relief of the bowels, and the administration of salicylate of soda in efficient doses in combination with such alkaline remedies as the condition of the urine may suggest," and I have been interested to see how far this ordinary routine treatment has been exemplified or departed from by those who have spoken. The object of the treatment is to diminish suffering, to lessen the duration of the disease, and to protect the heart. It is, of course, absolutely unnecessary in an assembly of practical men such as this is to speak of the necessity of keeping rheumatic patients in warm wrappings in a comfortable, well-ventilated room, and of securing a free relief of the intestinal secretions. I do thoroughly approve of the diet of patients being strictly liquid, and mainly milk, for a good many days. Dr. Burney Yeo's remark was a valuable one and one apt to be forgotten in hospital practice, and that is, "Let the patient have a good drink of water if he wants it." One sees in hospital wards the careful manner in which water is given as if it were a potent medicine instead of a soothing drink. With regard to rest in the treatment I feel bound to linger a little, although less to-night as so much has been said. I do think that the profession have not yet fully grasped the exceeding importance of absolute and prolonged rest in the treatment of rheumatic fever, especially, of course, when the heart is involved. The inadequacy of treating the patient by rest has largely affected the statistics of the salicylate treatment. A practitioner will give salicylates to a patient and in two or three days the patient is free from pain and does not see why he should not get up. Determination is required to make him keep at rest. The salicylate treatment relieves the *symptoms* of the disease and subdues many of its important features, but it does not cure the rheumatic illness, it does not shorten the duration of that illness. You cannot get out of the rheumatic illness under four or six weeks, and if, because the patient is relieved of pain he begins to move about he nevertheless is still a patient with latent rheumatic fever and may have a relapse and in all probability a relapse with cardiac complications. With children the slight joint affections often mislead the practitioner and the rheumatism may not be detected, with the consequence that relapses occur with cardiac complications. Dr. R. Caton was very emphatic about the importance of rest in the treatment of rheumatism. I may venture to say that I think a good deal of Dr. Caton's great success in the treatment of rheumatism is due to his having so early recognised the extreme importance of continued long rest throughout the rheumatic illness. Dr. Sibson, who was the first advocate of the 'rest' treatment in rheumatic fever, was curiously inadequate in his directions in regard to it, and his directions were that the patient should be kept quiet in bed "for a period of several days after the complete disappearance of the local inflammation of the joints." The point in the treatment of rheumatism is that so long as the tongue is coated, the urine is loaded, and so long as there is a trace, even the slightest trace, of pyrexia, people must be kept rigidly in bed in warm clothing and also for a period of a good many days afterwards even in the complete absence of any cardiac affection.

There is one little point in regard to temperature that is important. One so often hears it said that a patient has no fever of any consequence, that the temperature only runs up to about 99° F., or a little below, and you are told he is not feverish. But 99° in the mouth or the axilla is a morbid degree of temperature, and taken in association with the history of recent rheumatism or a slight endocarditis it is an absolute sign of the importance of preserving complete rest. As Dr. Maclagan said, inflammation in the valves of the heart is very slow to subside, and it is not a mere surface inflammation but affects the fibrous texture of the valves, which are ever in function: and when diminished in resisting-power by recent inflammation the extra strain upon them of several thousand impulses per day involved by the patient changing from the position of absolute rest to the upright posture, or sitting or moving, is enough to keep up the inflammation and to cause a deforming valvulitis. I remember well Sir William Jenner's memory-clinging words when he used to say in the clinical wards, "Children do not grow out of heart disease, they grow into it." That statement was mainly founded on the treatment of rheumatic fever in our hospitals and especially in children's hospitals where, at that time particularly, rest, complete rest, for a sufficient length of time was not observed. I do not know whether the rest treatment can be observed fully in children's hospitals, the want of it is an explanation to my mind of that statement.

Again, I would venture to say from clinical experience that those two most grave cardiac affections of rheumatic origin, mitral stenosis and aortic regurgitation, are valvular lesions which are scarcely ever met with in primary rheumatic illnesses—they are almost always found in those cases which have left the hospital after a primary attack of acute rheumatism and have returned some months later. These two lesions are the consequences of subsequent slow deforming valvulitis from strain put upon the valves before they have completely recovered from the primary rheumatic lesion. In my experience, and in that of many of those who have spoken to-night, primary endocarditis is a curable disease in a large number of cases if taken in time and if the patient is retained at rest for a sufficient time to allow the valve to make recovery before the extra strain or function is put upon it.

With regard to salicylates, if they do not do all that which was originally claimed for them, their usefulness cannot be gainsaid. Those who remember the controversies of some 30 years ago, when the relative values of alkalies, blisters, iron, mint-water, and cotton-wool wrappings were discussed, will agree that there was no very marked advantage in the treatment of the disease by any of them. As already said, it is the universal experience that salicylates do not affect the duration of the rheumatic illness, but they do reduce the temperature and relieve the joint affections. It would be idle to discuss the mode of action of the remedy with which we are after all somewhat imperfectly acquainted which neutralises, although it does not extirpate, the rheumatic poison, a poison of which we know absolutely nothing. The salicin compounds are certainly remote antiseptics of considerable power. Those who have watched patients taking considerable doses of salicylate will have noticed how long the urine can be left standing exposed to the air without undergoing decomposition. It is said that statistics prove that cardiac complications are more frequent in those who are taking salicylate and that relapses are more to be feared than under the alkaline treatment. I think that Dr. Ewart hit on the fallacy of the inference from these statistics when he remarks upon "the indirect risk that arises that we may be misled into over-estimating its anti-rheumatic powers and relax too early both treatment and diet."

It is said, again, that salicylates have no influence upon hyperpyrexia in rheumatism. I do not know that any drug has an influence on hyperpyrexia when it is established, but in my experience hyperpyrexia has enormously diminished as a complication of rheumatism since the introduction of the salicylate treatment. Dr. W. E. Wynter has been kind enough to look through the records of the Middlesex Hospital for the last 30 years. In the years from 1870 to 1876—that is, before the period of the salicylate treatment—there were 952 cases of rheumatic fever with 30 deaths, that is to say, there was an average of 136 cases of rheumatic fever every year with an average death-rate of four and a quarter. In this period there were 11 cases of hyperpyrexia of which one case recovered. In the remaining 21 years, from 1877 to 1897, all within the period of treatment by salicylate, there were 2552 cases of rheumatic fever admitted into the hospital with 27 deaths, or an average of 121 cases instead of 136 cases per year, and with a death-rate of one and a half in 121 as against four and a half in 136 In that period there were only six cases of hyperpyrexia, all of which occurred in the first two years and four of which recovered. There has been no death from hyperpyrexia in the hospital since 1889. My impressions have been thus borne out by the hospital records. Then, again, in the treatment of hyperpyrexia I have made it a rule after reducing the temperature by cold to adhere to the salicylate treatment. I think it will be found that where hyperpyrexia occurs in a considerable proportion of the cases the salicylate treatment has not been pushed very vigorously.

Pericarditis is spoken of as a common complication of rheumatic hyperpyrexia. My experience, and I should like to know if it is the experience of others, is to find in high temperature that it is common to hear a pericardial friction sound or a rough murmur at the base of the heart, which is found to disappear when the temperature comes down nearer to the normal range. I have come to regard with great suspicion such adventitious sounds when presented in cases with a temperature above 104° and wait till the temperature is lower, looking upon them as often due to some temporary dryness of pericardial membrane or some changed hæmic state.

There have been various statements as to the unfavourable effects of the drug, some maintaining that these effects are rather imaginative. I must confess that I do not agree with this opinion. I have observed a distinct case of renal hæmorrhage associated with salicylate treatment and I think Dr. Pye-Smith mentioned some cases also. Then, again, the occurrence of great slowness and great feebleness of the pulse is sometimes met with in people taking salicylates, so notably met with as practically to interrupt the treatment by salicylate. Now and again one meets with delirium with a falling temperature coming on in the course of rheumatic fever; that is in my experience always an untoward consequence of salicylate treatment and requires the treatment to be interrupted. With regard to the dosage various opinions have been expressed. I for my part should say that a 15-grain dose is better than a larger dose, but it should be repeated at sufficiently short intervals to get the patient under the influence of the drug. When too large doses are given at first the drug is apt to cause vomiting or other disagreeable symptoms. I fully agree with Dr. C. O. Gibbes that the influence of the drug should be maintained.

The effect of the discussion will be to rehabilitate alkalies in our good graces The alkaline treatment was tried in its thoroughness many years ago and was found wanting, and although it still lingers as a tradition in some London hospitals yet it has come to be softened down and to be mingled with the more efficacious salicyl treatment. Alkalies seem to be called for by the symptoms of rheumatic fever, but I should very much question whether they can have much influence upon that acidity which is said to be so potent in producing paralytic cardiac dilatation. For we must remember, at least I think I am right in saying, that the blood is never acid even in acute rheumatism; it may be less alkaline than is normal. As regards the sweat I have never observed the sweat of a patient to be rendered alkaline by the alkaline treatment even in cases where the urine is strongly alkaline. The urine is readily rendered alkaline, but I doubt whether it is of any advantage to make the urine, which is normally acid, alkaline in the course of the treatment of rheumatic fever. I should regard the usefulness of alkalies rather as increasing the oxidation of the tissues and promoting the elimination of morbid materials, whatever they may be, from the blood and should be inclined to give them in moderate doses.

With two exceptions, Dr. Donald Hood and Dr. Burney Yeo, opium has not been touched upon. It was at one time an important remedy in acute rheumatism. We do not now require to give opium to any great extent—it is useful for the first 24 hours for the relief of pain—but in myocarditis, in grave forms of endocarditis, and especially in pericarditis, the opium treatment is of immense value, its object being to cause organic rest, so far as organic rest can be given to an automatically moving organ, by diminishing the rapidity of the pulse and quieting the restlessness and agitation of the patient.

With regard to blisters very much has been said and I should attach much importance to Dr. Caton's views after 19 consecutive years' observation. The idea of treating the surface nerves which have reference to the inner organs, the area of distribution of which has been so ably pointed out by Dr. H. Head, is an attractive one. The possibility of producing a reflex vaso-motory control of the affected valves is a very attractive hypothesis, but I still think it is rather straining physiological therapeutics to the extreme point. An ounce of fact, however, is worth a pound of theory and Dr. Caton has found the application of small blisters useful in acute rheumatism, and one can only suggest its further trial. We all agree on the little value of digitalis in the acute cardiac affections of rheumatism. The treatment of the more chronic affections of the heart in rheumatism referred to by Dr. Sansom by regulated exercises and by saline baths seems scarcely to come within the range of the discussion. I believe he would agree with me that these therapeutical measures are unsuitable in the treatment of acute or sub-acute rheumatism with any active trouble in the valves.

I fear my remarks have been discursive, but I would say that for my own part I have derived the greatest possible interest and advantage in carefully watching this debate through and I think it is a discussion which will be of extreme practical help and value. It is a most important function of clinical societies, in my belief, occasionally to bring forward questions of this kind, to be discussed from a large point of view, collating the experience of many observers in order to formulate some efficient and valuable treatment of such diseases which are the more important because they are very common.

ON THE TREATMENT OF THE RHEUMATIC DISEASES OF THE HEART IN THE EARLY PERIODS OF THEIR MANIFESTATION.

A RETROSPECT AND AN ESTIMATE.

BY A. ERNEST SANSOM, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE LONDON HOSPITAL, ETC.

IT is of a distinct value that we should at certain periods—the intervals being not too short—take stock of our therapeutic resources. When we do so we ought to be careful to steer a middle course between the whirlpool of extreme enthusiasm and the rock of stolid obstruction. It is easy to be carried away by therapeutic optimism. It is not difficult to be too much unconvinced and to carry out too inflexibly the maxim, "*Et surtout point de zèle.*" It seems to me that it would be very difficult at the present time to find a subject of greater practical importance than that of the treatment of rheumatism. It has been determined with much wisdom that the best plan for obtaining good practical therapeutic data is to obtain the opinions of many observers. This way has the advantage of excluding many fallacies and of presenting the therapeutic problems from many points of view. My own contribution to the investigation will be confined to a consideration of the manifestations of rheumatism upon the heart and surrounding structures and a very brief estimate of the best practical methods of treatment which we now possess according to my own deductions—deductions which I, of course, consider as fallible and only to be adopted if confirmed by the experience of others. I do not think that this survey of the great question, the pathology and treatment of rheumatism—a survey which in point of time has occupied me more than 40 years and has ranged over the fields of practice in a children's hospital and in general hospitals, in general practice and in the private practice of a hospital physician—can be wholly valueless. At any rate, I am thankful for the opportunity of giving my confession of the faith that is in me.

PRELIMINARY CONSIDERATIONS: MEANING OF THE TERM "RHEUMATISM."

I do not intend to offer any observations on academic questions. The meaning of the word "rheumatism" as it affects the heart will be manifested with more or less perspicuity in the course of this inquiry. I cannot help saying, however, that a clear mental picture of the disease must of necessity be in the mind of the medical practitioner before there can be any satisfactory solution of the problems of treatment. The differentiation of rheumatic diseases and the exclusion of the non-rheumatic have notably cleared the blurred picture that was presented to me in the earlier days of my medical life. Scarcely more than 20 years ago suppurating joints were described as rheumatic. Now we know—and knowledge is advancing—that there are many forms of arthritis besides the rheumatic forms. I need scarcely say that it is only within recent years that infective (septic or ulcerative) endocarditis has been accurately differentiated from the rheumatic form of the disease, in which, however, it not infrequently occurs as an epiphenomenon.

THE FIRST CAUSE OF RHEUMATISM.

Though we have no precise demonstration of the micro-organism or micro-organisms that effect the first morbid changes there is a general disposition to conclude that the disease is due to an infective agency which is correlated with the pathogenetic micro-organisms of the infectious diseases. From evidence which I have observed it has seemed to me that in rheumatism the early influence of tonsillitis (often a trivial unnoticed superficial lesion of the mucous surface of the tonsil) has been underrated. At any rate it is well that further investigation should be made upon this point, for the denuded surfaces of the upper air-passages offer a very favourable ground for the cultivation of micro-organisms, and the occurrence of scarlatinal or post-scarlatinal arthritis presents an argument from analogy.

SLOW EVOLUTION OF THE MORBID PROCESS.

Whatever the nature of the primary agency the resulting toxic effects must be very subtle in their early manifestations and very protracted in their course. A considerable array of evidence shows that the forms of heart disease, essentially rheumatic, may be induced in the fœtus in utero whilst the mother shows no notable signs of any rheumatic disease.[1] In the earlier years of life diseases which without doubt are of rheumatic form occur unnoticed and unrecorded. I am quite sure that endocarditis with resulting valvulitis causing persistent and increasing lesions of the heart-structures may thus occur. To explain the course of events on the hypothesis of an infective agency (a pathogenetic micro-organism) we must, I think, take one of two paths of thought: either the toxins are very slowly evolved and so for months and years after the first importation of the microbes produce morbid changes, sometimes in the heart-tissues, sometimes in the pleuræ, in the alveoli of the lung (broncho-pneumonia), in the fibrous tissues in various situations, in the skin, the blood, and the central nervous system; or else the toxins first evolved so affect the nervous mechanism as to induce a perversion of metabolism whereby an autogenetic morbid product is produced in the blood, the period of manifestation of such perversion of metamorphosis lasting during the period of childhood and maturity, for the tendency to the advent of true rheumatism ceases at the age of 35 or 40 years. Whatever hypothesis we adopt we must agree that successive waves of recurrence of the disease—storms followed by calms—are manifested during the months and years of life of the individual affected.[2] If it be, as I have said, that the diseases of the heart met with in the course of rheumatism are so subtle in their first manifestations, so symptomless, so protracted in their course, it should cause little surprise that the statistical method has not hitherto demonstrated in an absolutely convincing manner that modern therapeutic methods have succeeded in controlling or preventing the disease of the heart due to rheumatism

Though statistical evidence, however, fails to show that the prevalence of heart diseases resulting from rheumatism has been unmistakably reduced I am convinced that such diseases have been powerfully influenced for good by modern methods in a way that statistics do not and cannot demonstrate.

[2] The Nature of True Rheumatism, Clinical Journal, Dec. 7th, 1892, p. 81.

The distinct advances in therapeutics which I consider to be established by satisfactory evidence are: (1) the employment of salicin and the salicin compounds; (2) the use of the icebag and cold applications; (3) the employment of physical means for directly influencing the nerve mechanism; and (4) the judicious employment of bathing, hygienic methods, massage, and mechanical exercises.

THE SALICIN TREATMENT.

If this treatment fails to prevent the manifestation of rheumatic disease of the pericardium and the heart it is at any rate proved by a mass of convincing testimony that it promptly takes from acute rheumatism its painful terrors, ministers to comfort, and thus brings about that systemic calm which is of the first importance in obtaining a good result in cases of heart disease. The routine plan which I adopt in the case of an adult is to administer the pure salicylate of sodium in 20 grain doses, with five-grain doses of ammonium carbonate, or 20-minim doses of aromatic spirit of ammonia in an ounce of camphor water every two hours until six doses have been taken or until temperature has fallen and pain has ceased; subsequently the administrations are reduced to every six hours or every eight hours. It has been said[3] that sodium salicylate is incompatible with free ammonia, ammonium carbonate, or aromatic spirit of ammonia, but I have investigated this point and find that the mixtures of these substances show no decompositions and are perfectly well taken by the patients throughout the whole period of treatment. I have combined the alkaline carbonates, especially sodium carbonate in 20 grain doses, with the mixture in some cases, but I have not observed that this is in the early stages of treatment of any distinct advantage. Any recurring wave or storm of the disease is treated as the early symptoms and treatment is kept up for three to six weeks. I have very rarely observed signs of intolerance of the drug, but in a small minority of cases I have employed the dithiosalicylate of sodium in three grain doses every eight hours in a cachet or in chloroform water with extract of liquorice. It is very rarely, however, that the sodium salicylate acts in any way other than beneficially and the toxic symptoms are sometimes wrongly ascribed to the drug as they are really due to the disease for which the drug is administered.[4] In all cases of acute rheumatism in which the features are a rise of temperature and painful affections of the joints I am convinced that the treatment by the salicylates is the best that can be adopted. With this there must be combined the policy of perfect rest in bed.

RHEUMATIC PERICARDITIS AND ITS TREATMENT.

The cases of rheumatic pericarditis which I have observed convince me that there is an important preliminary consideration before any estimate can be made of the value of a given line of treatment I mean that there is an extraordinary variation in different cases in the nature, the extent, and the intensity of the symptoms of the disease. In some cases these symptoms are so grave that the patient seems, and is, in the extremest peril hour by hour; in other cases the signs and symptoms are so trivial as to be unnoticed and the affection is only found out on physical examination. The perilous, or even fatal, symptoms may be manifested at any stage of the disease. For instance, I have been called to a patient in acute delirium whose ravings have disturbed a whole ward. The delirium has been followed by prolonged epileptiform convulsions. In the course of a few days rheumatic pericarditis has been evidenced and has continued until recovery. In another case a patient was admitted in a typhoid state with diarrhœa and passage of some blood. I found the physical signs of pericarditis. After 18 days the adverse signs as well as the pericarditis had disappeared. Seven days afterwards there was a typical attack of polyarticular acute rheumatism. In many cases there are signs of great pain and distress, intense uneasiness at the præcordium and epigastrium, an extreme hyperæsthesia of the skin over the thorax, paroxysmal attacks of suffering of the nature of angina pectoris, difficulty of swallowing, vomiting, extreme breathlessness, terror depicted upon the countenance, lividity and cyanosis, with disturbances of breathing. I find these to be wholly disproportionate to the extent of the disease. There is in many cases a morbid acceleration of the breathing-rate (tachypnœa), and in many cases also orthopnœa with great distress and paroxysmal dyspnœa. I must conclude with Dr. D. B. Lees that in these cases the difficulties are caused by an involvement of the nerve-mechanism, an irritation of the sub-pericardial nerves whereby the respiratory centre is influenced by a morbid reflex. In other cases there is an extraordinary absence of symptoms of discomfort. I have observed a boy who has manifested the physical signs of a long-continued pericarditis and yet has complained of no subjective symptoms whatever. The boy could be kept comparatively quiet, but could not be induced to remain in bed. In a large number of cases I have traced the early signs and a full development of a typical pericarditis in the course of rheumatic fever without there being any noteworthy symptom to indicate the involvement of the pericardium in the disease. I cannot doubt that the true explanation of the immunity from grave symptoms in these cases is to be ascribed to the fact that the sub-pericardial nerves were not involved in the disease. In the other cases not only the difficulties of breathing, but the dyspnœa, the hiccough, the hyperæsthesia, the symptoms of angina pectoris and the heart failure are to be ascribed to an involvement of the structures of the nervous mechanism.

In the treatment of cases under my own observation I have very rarely found it to be of benefit to suspend the administration of the salicylates if these drugs have been in use for the painful and febrile stages of rheumatism. As an adjunct to such treatment (or in the absence of articular symptoms and of fever in substitution for it) my evidence points strongly to the value of the use of the icebag as advocated by Dr. D. B. Lees. In the case of pericarditis with typhoid symptoms already mentioned (that of a girl 17 years of age) when the signs were very great dyspnœa with irregular rhythm of respiration and compression of the lower lobe of the left lung by the distended pericardium, the icebag treatment was pursued for 16 days; then the signs of pericarditis disappeared. In another case (that of a girl aged 18 years), there was a great protraction of symptoms, the pericardium continuing greatly distended, and there was a friction sound for so long a period that I feared that there must be tuberculous pericarditis. The treatment was chiefly the prolonged use of the icebag suspended over the præcordium, but on three occasions six leeches were applied in addition. Recovery was almost complete when the patient was discharged after eight weeks of treatment. I have subsequently examined the patient and have found the heart to be perfectly healthy. Leaving out all statistical data I have no doubt in my own mind that in rheumatic pericarditis the use of the icebag over the præcordium has coöperated with the internal administration of the salicylates to be a treatment of high value—the best I know—for rheumatic pericarditis. It is now a routine practice with me. Usually the cold application is grateful to the patient; it is evidently anæsthetic and tends to subdue the pain and distress. In some cases it is not well tolerated. The patient irritably gets rid of the application and then I am sorry, but I do not push the treatment For many years I adopted the plan of blistering the præcordium, but I think that this procedure is practically without influence both in regard to the comfort of the patient and the prevention of lasting disease.

THE SWOLLEN HEART OF RHEUMATISM.

From observations which I have made during a series of years I have come to the conclusion that the text-book descriptions of pericarditis and endocarditis do not convey to the mind a complete picture of the phenomena of rheumatism affecting the heart. Even in the absence of any signs of pericarditis, though sometimes concurrently with these, the whole heart may become enlarged. These enlargements are often followed by recessions, so there may be the physical signs indicating a great dilatation of the heart, both right and left chambers, at a given time, and 24 hours afterwards the heart may have receded to its normal limits. I have described such cases in International Clinics, 1894, p. 12. I need scarcely say that these views have been corroborated, with many precise observations and much addition to our knowledge, by Dr. D. B. Lees and Dr. F. J. Poynton[5] It has seemed to me that these enlargements and recessions of the heart, recurring as they do, are closely analogous to the phenomena that occur in the rheumatic joint. There is not of necessity pericarditis as ordinarily understood, nor is there endocarditis, but the whole heart is swollen, for a time hyper-vascular, infiltrated with exudations, and its muscle enfeebled, and after a limited period, which may be even as short as 24 hours, there is rapid absorption of exudation and a restoration to the normal. There are successive storms of rheumatism in the heart as in the joints.

[4] The Treatment of Rheumatism, International Clinics, 1894, vol. i, p 9

[5] Transactions of the Royal Medical and Chirurgical Society, vol lxxxi, 1898, pp. 401 and 419.

From collateral evidence I think it probable that disturbances of the nervous mechanism of the heart are causally associated with these phenomena. I have observed an acute dilatation of the heart with rapid subsidence occur with signs that indicated neuritis of the vagus. In this case the cause was not rheumatism. I do not suggest that rheumatism ever induces neuritis of the vagus or any morbid affection of its central parts. I have no experience that the disease, uncomplicated, influences these structures, yet I think it highly probable that just as in some cases of pericarditis the sensory disturbances and the perversions of the cerebral mechanism are reflex and due to a morbid irritation of the sub-pericardial nerves, so in the swollen heart the acute dilatation is due to a temporary irritation of all the local nerve structures of the heart and pericardium. For many reasons I believe that the hypothesis of any direct weakening of the cardiac muscle, any form of myocarditis, is inadmissible.

TREATMENT OF THE SWOLLEN AND DILATED HEART OF RHEUMATISM.

In the first place I consider that the treatment by the salicylates should be continued and even the frequency of administration of the doses should be increased or be as in the early stages of the treatment of acute rheumatism. The icebag to the præcordium may also be applied or re applied. In fact, in these points the treatment should be as for rheumatic pericarditis. It must, however, be remembered that on many occasions the case may put on a very grave aspect, and the patient may be in immediate peril. In such case I am emboldened to say that I have never seen any good results from the administration of digitalis (or digitalin) and I think I may say from experience of the past that I have sometimes seen much to regret from its employment. Sir T. Lauder Brunton and Dr. Cash have shown that digitalis does not manifest its usual good effects upon the heart muscle when there are conditions of pyrexia.[6] My experience from a clinical point of view confirms this statement. So also, according to my own observations, the drug fails to exercise its tonic power on the heart muscle (although it may induce vomiting and other toxic symptoms) when the structures are infiltrated with morbid exudations.

Failing cardiac power is best treated by the frequent administration of ammonia and similar diffusible stimulants in small doses with camphor water or by musk in from three to five grain doses, or tincture of sumbul in 20-minim doses in camphor water, or by hypodermic injection of one-fiftieth or one-thirtieth of a grain of strychnine (sulphate, hydrochloride, or nitrate).

EMPLOYMENT OF THE CONTINUOUS GALVANIC CURRENT IN THE AREAS OF THE VAGI.

I have had considerable evidence to show that this may be a valuable agency in the treatment of the rheumatic heart in its more severe manifestations. For instance, in a case of extreme severity in which I observed recurring enlargements of heart and extremely critical symptoms I adopted in addition to the salicylate treatment the administration of the constant galvanic current from eight cells to the course of each vagus nerve for six minutes three times daily. The anode—a flat metallic plate covered with soft tissue and moistened with hot water—was applied over the nape of the neck, and the cathode—a metallic tissue-covered button similarly moistened—was pressed over the skin of the neck outside the larynx and trachea, or moved slowly up and down from the mastoid process to the clavicle on the right and the left sides alternately. The patient made a most satisfactory recovery. The dilatations of the heart subsided to the normal, the subjective symptoms passed away, and the patient returned to the active duties of life, although there was a murmur of aortic regurgitation. I have seen him, more than 12 months after his illness, hale and strong and oblivious of any imperfection in his heart-valves, and indeed such imperfection is but very slight. I have observed good results in several other cases thus treated, but I cannot, of course, claim for this mode of treatment the efficacy that I have considered to be established in regard to the other therapeutic measures I have mentioned. It is yet *sub judice*.

RHEUMATIC DISEASE OF THE VALVES OF THE HEART.

I have written down my experience which tends to show that the morbid changes in the pericardium and in and about the muscular structures of the heart often occur insidiously and are not betrayed by characteristic symptoms. I assert this still more strongly of rheumatic affections of the valves. In the pronounced rheumatic storms affecting the heart, when there is pericarditis or the swollen heart of rheumatism, it is common, though not invariable, for the endocardium and the valves to be involved. In such case the area of lining membrane of the heart being so extensively diseased, the morbid changes occur chiefly in the mitral valve, the chordæ tendineæ, the musculi papillares, and all the structures in the neighbourhood of the valve, and the result is usually mitral incompetence.

The patient departs from our observation with the systolic murmur of mitral regurgitation and resulting changes which may be compensatory in the left auricle and the two ventricles. But even in a case like this there may be a fallacy. I have known cases in which an apical systolic murmur was manifested during and after pericarditis so that exceedingly good observers had no doubt that there was mitral valvulitis with incompetence and yet the necropsy showed pericarditis only with no involvement of the mitral valve in disease. In such cases I believe the murmur to have been due to an enfeeblement of the heart muscle and especially of the papillary muscles. If there had been a recovery from the pericarditis the murmur and all physical signs of mitral regurgitation would have passed away. In many cases, however, the patient who has suffered from acute rheumatism goes away from our observation apparently recovered. Perhaps the last notes taken state that the physical signs in regard to the heart are normal—the sounds well-pronounced and no murmurs. Yet when the patient comes under observation again after the lapse of some months—no rheumatic symptoms having been manifested in the interval—there is unmistakeable evidence of mitral regurgitation. The disease processes in the valve and *surrounding structures have been* long drawn out, slow, insidious, and unmarked by symptoms. By no means infrequently the very period of commencement of the disease has not been betrayed by any symptom whatever.

When there are any signs, physical or rational, which lead to the diagnosis of endocarditis during acute or sub-acute rheumatism I find no *reason to modify the treatment* by salicylates, by icebag, &c., which I have already described. After the patient has entered into convalescence, however, much may occur to induce or to increase disease in the *valvular structures* of the heart without the patient being aware that any disease is in process. It follows, first, that a very guarded opinion should be given as to the presence of valvular disease in rheumatic subjects; secondly, that a patient who is the subject of rheumatism should be induced to submit himself to physical examination at fairly frequent intervals, notwithstanding the absence of symptoms. Then come the questions of hygiene and general management in these cases, for medicinal treatment is probably of far less importance than these.

Harley-street, W.

ON THE ABORTIVE TREATMENT OF SUPPURATION OF THE EYEBALL.

By SIMEON SNELL, F.R.C.S. EDIN.,
OPHTHALMIC SURGEON TO THE SHEFFIELD ROYAL INFIRMARY; PROFESSOR OF OPHTHALMOLOGY, UNIVERSITY COLLEGE, SHEFFIELD.

I WISH in this short note to direct attention to a mode of treating suppuration of the eyeball which is not as widely known, judging by the text-books, as in my opinion it merits.

In a large ophthalmic clinic suppuration of the globe is by no means infrequently met with. It is due to sepsis, but the immediate cause may be very varied. Amongst the causes may be mentioned penetrating wounds of the globe with or without the lodgment of a foreign body, abrasions and wounds of the cornea, either accidental or the result of operation, burns of the cornea, &c. Pan ophthalmitis may also be due to metastasis from a variety of conditions. The clinical picture of suppuration of the eyeball is characteristic. There are considerable swelling of the lids, enlargement and protrusion of the globe, and swelling of the conjunctiva. In cases arising from metastasis the cornea would be clear and a yellowish appearance denoting the deposit of lymph in the vitreous cavity would have been visible at an earlier period than that just depicted. The pain is most acute and long continued and the condition may be regarded as lasting for at least from four to six weeks.

---

[6] Address on the Connexion between Chemical Constitution and Physiological Action. Brit. Med. Jour., Aug. 14th, 1885, p. 323.

To relieve pain and to cut short the disease are the ends to which treatment should be directed. In the opinion of many enucleation of the globe is not admissible and it is almost entirely in such cases that the fatal instances associated with excision of the eye have occurred. It was laid down long ago by Von Graefe that the excision of suppurating eyes should be avoided owing to the likelihood of meningitis ensuing. The report of the committee of the Ophthalmological Society (1898) which was appointed to consider the relative values of simple excision of the eyeball and of the operations which have been substituted for it, showed the danger of excision in this condition, but in the large numbers dealt with it would nevertheless appear to be, comparatively speaking, of very infrequent occurrence. It has been held by some that the careful use of antiseptics at the time of operation and afterwards would obviate the danger alluded to. I am hardly, however, of this opinion. For many years antiseptics have been carefully used, as a matter of routine, in my practice in all cases of enucleation, but I have not felt that their employment has given me such a sense of security that I should, if other means are available, excise a suppurating globe, especially when the weight of opinion is strongly against such a course.

A better and safer plan, in my opinion, is to deal with the eye on general surgical principles. An abscess elsewhere would be opened and drained and a similar condition affecting the globe should be treated in like manner. I hardly think that this principle has been, up to now, sufficiently appreciated. Text-books—at least some of them—it is true, make mention of incising the cornea or sclerotic and refer, often vaguely, to evisceration in the treatment of suppuration of the eyeball. The plan here advocated is, however, definite both in procedure and in the results which it affords. It is not an evisceration in the sense that Mules's operation is, for no glass globe is inserted into the scleral cavity. It is more like the procedure advocated by Noyes, Von Graefe, and Bunge, and called by some "exenteration," but it will be observed that no stitches are inserted into the sclerotic and it may be that their non-use has been a reason for the absence of the excessive reaction and the prolonged stay in hospital which have been mentioned by some operators.

I have notes before me of suppuration of the eyeball occurring in the following conditions in which the operation has been done: (1) after ulceration of the cornea; (2) wound of the cornea (in a young girl); (3) after cataract extraction, with lacrymal obstruction; (4) wound of the cornea by a piece of coal; (5) suppuration of the cornea, after injury from blasting; (6) foreign body in the eye; and (7) wound of the sclerotic by a hat-pin. I have, however, done this operation for many years and therefore the total number of instances would be a large one. In all these cases the plan adopted was as follows. Ether having been administered, the cornea, unless it is already destroyed, is divided across by a cataract or Beer's knife. The next step is to remove the remains of the cornea up to the sclerotic, and this can be well done with scissors. Some of the contents of the globe may have escaped by this time, and the remainder, consisting of thickened half-gelatinous-looking masses, can be drawn out with forceps. After removal of these portions, which are readily taken hold of by forceps, Mules's scoop may be used to aid further in the cleaning of the interior of the globe or cotton-wool and forceps can be employed to wipe out the contents. Lastly, sublimate solution is freely syringed into the eye cavity until all the contents have been removed or washed away and only the bared sclerotic remains. Gauze is lightly packed into the eyeball and a bandage is applied. Almost immediate relief from pain follows the operation, with no return, and the swelling of the orbital tissues gradually subsides. The dressings are changed on the night of the operation, and during the next few days the eye is syringed twice a day and the gauze is re-applied. For about the first three days there is some discharge, after that practically none. The patient is even then better than he would have been at the end of some weeks if the disease had been otherwise treated. He will, as a rule, be fit to leave the wards in about 14 days. Ultimately a small button is left in the orbit, which is a better foundation for the adaptation of an artificial eye than if enucleation had been performed. I have seen no ill results follow the operation nor should I apprehend them. It is notorious that sympathetic ophthalmitis does not follow suppuration of the globe, and the procedure here advocated forestalls the completion of this condition. In one case some sloughing of the sclerotic occurred but it did not do more than somewhat delay recovery.

Sheffield.

A CASE OF LYMPHATIC LEUKÆMIA.

By M. H. SPENCER, M.D. CANTAB.

THE following case seems to be worthy of record on account of the comparative rarity of the affection.

The patient was a tall, well-made man, aged 38 years, who had led a healthy life and had been accustomed to athletic exercises. There was no previous history of malaria or of any other serious illness. In August, 1899, he complained of pain and tenderness in the right heel which interfered with walking. At this time he appeared otherwise to be in perfect health. The pain about the heel soon passed off, but returned again in the autumn, and a physician who saw him, regarding the symptom as a gouty one, placed him upon a somewhat restricted diet. Towards the end of November he began to feel a little poorly, but was able to play golf and follow his usual pursuits. On Dec. 11th I was called in to see him and found him complaining of pain in the left side of the chest and in the left supra-scapular and infra-costal regions. On the previous day he had been driving in a dogcart and as he felt cold he got out and tried to run for some distance, but was unable to do so on account of shortness of breath and a feeling of exhaustion.

Examination revealed no abnormal signs over the heart o lungs. The spleen was considerably enlarged, reaching nearly to the umbilicus, and was rather tender. The liver was als enlarged and was palpable for the breadth of two finger below the ribs. No enlargement of the lymphatic gland was detected. The urine was loaded with urates but wa free from albumin. There was well-marked anæmia. A rough examination of the blood showed an excess of lymphocytes. The pain in the left side which had been first complained of soon disappeared, but the patient developed a troublesome dry cough which kept him awake at night and caused pain in the splenic region. The anæmia increased in intensity, he became very breathless on slight exertion and rapidly lost strength.

On Dec. 30th an ophthalmoscopic examination revealed numerous blotchy hæmorrhages in both retinæ with som fluffy white patches. There were no marked broadening o the vessels or orange tint of the fundus and no optic neuritis The temperature soon began to rise at night falling to norma or subnormal in the morning. This type of temperature wa maintained until the end. By Jan. 14th, 1900, the weaknes had greatly increased and the pallor was intense. Ther was no dyspnœa whilst the patient was at rest, but h was extremely breathless on the slightest exertion. Ther was now some enlargement of lymphatic glands in both groins and a few, of about the size of a filbert, could be felt in the axillæ and in the posterio triangles of the neck. Subconjunctival hæmorrhages had occurred in both eyes, but there was no bleeding from the gums or from the stomach or bowels. The gums wer pale and slightly spongy and were retracted from the teeth but the marked gingivitis described in some cases of lymphatic leukæmia was not present. There was tenderness on pressure along the anterior surfaces of the tibiæ and ove the manubrium sterni. At night the patient suffered from profuse perspirations and the cough continued, causing a times troublesome retching. In the absence of any physica signs over the lungs it was thought that this dry cough might be due to pressure from enlarged bronchial glands On Jan. 18th Dr. Louis Jenner, who kindly examined th blood, made the following report: "Without counting it i obvious that the white cells are greatly in excess of normal

A differential count shows that the fine granulated oxyphils (polymorpho-nuclear-neutrophiles) are present in a ratio of 34 per cent. (normal, from 70 to 72 per cent.). The lymphocytes number 63 per cent. (normal, from 22 to 24 per cent.); these are of various sizes. The eosinophiles number 2 5 per cent. (normal, from 2 to 4 per cent.); the mast cells number 0 25 per cent. (normal, anything to 0·5 per cent.). There were, however, many destroyed leucocytes which I could not classify, but which for the most part were probably lymphocytes. There were a great number of nucleated red cells." The main features, then, of the blood were (1) a diminution in the number of the ordinary leucocytes (fine granulated oxyphils); (2) a great increase in the lymphocytes; and (3) the presence of a number of nucleated red cells.

The progress of the case was now steadily towards a fatal termination. On Jan. 25th there was some free fluid in the abdominal cavity. The size of the liver had increased, and the lower edge reached as far as the umbilicus. The spleen remained about stationary in size. There were considerable loss of flesh and profound exhaustion. There were several syncopic attacks. The mind remained clear till within 24 hours of his death which occurred on Feb. 2nd, and which was preceded by several hours of unconsciousness. The patient was treated with arsenic from the first, but the drug seemed to have no effect whatever upon the course of the disease. There was no post-mortem examination.

The reported cases of this form of leukæmia vary considerably in the clinical picture they present. In some the enlargement of lymphatic glands is a prominent feature; in others, the gums have been much affected and an acute stomatitis has been the first symptom complained of. They, for the most part, however, seem to run an acute course to a fatal termination, and the case I have recorded is no exception to the rule, for my patient died within two months of seeking medical advice. The enlargement of the spleen is generally only moderate in extent. It seems probable that the pain in the heel and pains in the left side of the chest which the patient complained of may have been dependent upon defective elimination and excess of uric acid. The point of interest in connexion with the blood is the presence of a large number of nucleated red cells. In the spleno-medullary form of leukæmia their presence is the rule, but in the lymphatic form they are most generally absent. The excessive enlargement of the liver accompanied by moderate ascites is also a feature of interest in the case.

North Kensington.

NOTE ON THE SUPERFICIAL AND DEEP REFLEXES.

BY JOHN M. MACCORMAC, M.D. DUBL.,
HONORARY PHYSICIAN TO THE VICTORIA HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, BELFAST.

SUPERFICIAL and deep reflexes as an additional means in the diagnosis of the principal forms of mental disease comprise a subject which, so far as I am aware, has not received attention in the United Kingdom. The conclusions I have arrived at after careful observations for many years are much in harmony with those of Agostini.

1. Let me first say a word on the subject of crossed knee-jerks. If the patellar tendon on one side be struck the opposite leg will be adducted mainly by the action of the crureus and vastus internus, which muscles are seen to contract even when the movement is slight. This patellar jerk is a true reflex, and I have observed that in certain forms of sclerosis of the spinal cord a slight percussion will cause the knees to knock together and at the same time the arms are adducted. These actions soon lessen and pass into a state of tremor which gradually disappears. 2. My observations on the superficial and deep reflexes in their relation with the modification of painful sensibility in mental disorders have shown me that the formulæ of Agostini correspond in a general way to the state of the reflexes in each of the principal forms of mental disorder and in consequence are valuable in the diagnosis of these affections.

In general paralysis of the insane the condition of the reflexes varies in the different stages of the disease. In the initial stage of this disease there is generally a weakening of painful sensibility and of the cutaneous reflexes with the exception of the plantar reflex. On the other hand the deep reflexes are exaggerated. In the second stage of the disease the plantar reflex is very markedly exaggerated and the other reflexes both deep and superficial are increased, the tendon reflexes being still more marked than in the first stage. In the third stage of the disease all the reflexes become weaker until they finally disappear. During an epileptiform attack the superficial reflexes are decreased or abolished, but the tendon reflex is exaggerated, and is often accompanied by fibrillary contractions which may be transmitted from a limb to the trunk and then may pass to the limbs of the opposite side.

In epileptic insanity sensibility to pain as well as the reflexes produced by stimulation of the skin and mucous membranes are generally lessened, but the tendon reflexes are normal. After some convulsive attacks the tendon reflexes are increased, whilst the cutaneous reflexes are considerably weakened, with the exception of the plantar reflex, which is augmented and may be associated with trembling or even with epileptoid movements of the foot. Hypochondriacs and neurasthenics generally present an increase of all reflexes both superficial and deep. In hysteria there is a decrease of painful sensibility and of the cutaneous reflexes. In alcoholic paralysis painful sensibility and tendon reflexes are exaggerated, whilst the cutaneous reflexes (except the plantar reflex) are weakened. In acute mania the reflexes are normal. In secondary dementia all reflexes are exaggerated. In melancholia painful sensibility and cutaneous reflexes are normal, whilst the tendon reflexes are exaggerated. In the stage of melancholic stupor painful sensations, which on superficial examination may appear feeble, are in reality normal, the cutaneous reflexes are feeble, and the tendon reflexes are exaggerated.

From the above statements we see how very differently tendon reflexes and cutaneous reflexes act, and this we can understand when we consider that the two acts of reflexes are represented in the spinal cord by separate systems, one of which may be affected while the other remains normal.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

EXTRAORDINARY CASE OF THE LOSS OF BOTH EYES, ONE AFTER THE OTHER, FROM SIMILAR ACCIDENTS.

BY ALBERT BENTHALL, F.R.C.P. EDIN.,
HEAD OFFICE MEDICAL OFFICER OF THE OCEAN ACCIDENT AND GUARANTEE CORPORATION.

IN the year 1896 and also this year, claims having been made, I was asked to examine the injured person and to report. For this purpose I held various consultations with the surgeons connected with the case and the following history is compiled from my notes.

On Jan. 3rd, 1896, a grocer's assistant, aged 41 years, when in the act of washing his face about 9 A.M., accidentally "put his finger in his right eye." On the 4th Mr. Llewellyn of Whitechapel was called in and he found "laceration of the cornea with effusion of blood under the conjunctiva." Suppurative inflammation of the eyeball resulted and on the 13th the eye was enucleated by Mr. Waren Tay at the London Hospital, the house surgeon in charge of the case being Dr. F. B. Hutter.

On Feb. 24th, 1900, at 7 P.M., the same man in washing his face struck his left and only remaining eye with a finger nail, this time not only lacerating the cornea but injuring the deeper structures, for on Dr. Sullivan of Holloway-road being called in he found "a penetrating wound of the cornea with the iris prolapsed and entangled in the wound." The patient was sent again to the London Hospital and iridectomy was performed by Mr. Waren Tay, Dr. Russell Howard being the house surgeon in charge. On March 19th, the day of my examination in consultation with Dr. Howard, there was a sloughing wound of the cornea, nearly in the centre of the pupil, rather over a sixth of an inch in diameter, est of the cornea being opaque and the conjunctiva ested. Mr. Waren Tay had not, on the date of my ination, decided to enucleate, desiring to give the at every chance of retaining some kind of vision if, by any possibility, such could be obtained by operation a year or more hence. I reported the whole facts to the Ocean Accident and Guarantee Corporation and the directors at once decided to admit and pay the claim, made under the general accident policy held by the patient, without keeping him in suspense until the sight of the eye was absolutely proved to be lost for ever.

This particular accident as occurring to one eye is not uncommon, but in all my experience I have never examined or heard of a case in which a man has lost the sight of both eyes from two separate similar accidents such as are here recorded.

Cockspur-street, S.W.

DEATH FROM CARBON DIOXIDE POISONING IN A BREWERY.

BY W. SCOTT THOMSON, M.R.C.S. ENG.,

ASSISTANT SURGEON, RHYMNEY WORKS.

ON March 2nd an inquest was held at Rhymney, Mon., *concerning the death of a well-built, sober*, industrious man, 25 years of age, employed in the Rhymney Brewery. It appeared that his duty on the day when he met his death (Monday, Feb. 26th) was to clean out a vat, or "piece" in brewing parlance, as he had been accustomed to do once or twice a week for the past six months. The vat in question was eight feet in depth and six feet in diameter, having a manhole 18 inches square, an almost obsolete pattern, the modern one being large and shallow. The vat was used for storing beer prior to "racking." The beer was drawn off on the previous Saturday morning, leaving a sediment or "slummage" of a few inches in depth at the bottom. The vat was then flushed with water and the cover put on the manhole some time in the afternoon—it is said by the deceased man himself—and it remained closed till 6.15 A.M. on the Monday. The object of covering up the vat was to facilitate the subsequent cleaning, as otherwise the sides became dry. After removing the cover and allowing the hose to run into the vat for 10 minutes the man was seen to enter the vat with a lighted candle in his hand. About 20 minutes or 25 minutes later a cellarman, wishing to borrow the mop, called out to him and, receiving no answer, went up to look for him when he saw him lying on the bottom of the vat face downwards with the ladder, which had fallen on its side, resting up against his body. The candle was subsequently found on the bottom. This is an important fact, as it indicates that the man was overcome before or shortly after he had reached the bottom—the custom being to stick the candlestick into the side of the vat, a spike being attached to it for that purpose. Having called for help and procured another ladder from an adjacent office the cellarman descended the ladder, followed by another man. They hitched a rope round the deceased's arm and with the aid of some other men got him out of the vat in about three minutes when I was immediately called and arrived on the spot within a quarter of an hour. The condition of the body was as follows. The heart had ceased to pulsate, there were no visible respiratory movements, and there was some frothy fluid about the mouth and the nostrils. The skin was pale, the lips and eyelids were slightly cyanosed, the eyes were half open, the pupils being widely dilated, and the expression of the face was calm and placid. The anterior surface was cold, whilst the back was fairly warm and there were no marks of injury. After having the man suspended head downwards, when a small quantity of fluid, not of a frothy character, escaped from the mouth, I performed artificial respiration by the Silvester method for 40 minutes but without success. During the manipulation froth exuded from time to time from the nostrils.

An examination of the vat showed, besides the candlestick on the bottom already mentioned, a certain quantity of water which, owing to a warp, was in some places three or four inches in depth and in others entirely absent, and it was in a pool that the deceased's body was found with the face downwards. In my evidence I stated that all the sigr pointed to death from suffocation, but whether the man ha been rendered insensible only by the carbon dioxide an then drowned or had been poisoned by the carbon dioxid only I could not positively say. The latter, however, wa quite compatible with the signs. The coroner (Mr. J. I Walford) in a very able summing-up dismissed the ide of death being due to syncope or a fall from th ladder, there being no evidence whatever that the ma had suffered from heart disease, and there were no mark of injury on the body or signs on the bottom of th vat of the ladder having slipped. He therefore considere it to be a case of poisoning by carbonic acid ga *This, however, does not seem so simple, as two me* went down within half an hour at the most and stated tha they felt no inconvenience from the fumes; but probably th fall of the man and his pulling the ladder down disturbe the dense layer of carbon dioxide, which, being heavy, i always most concentred in the lowest part of a mixe atmosphere. It was also stated by the widow of the decease that he had frequently complained to her of the effects o the fumes, so much so that he said it was not safe to go int the vat without a man being outside to watch. The tw witnesses who pulled the body out had on many occasion cleaned the vat and they stated that it did not affec them. It seems hardly likely that the deceased had an idiosyncrasy, as the effect of carbon dioxide is chemica rather than physiological. Would a post-mortem examinatio and a spectroscopic examination have been of any scientifi value? Hardly; and, moreover, as the coroner said, a medica man has a fixed legal fee of a guinea, while an analys can charge what he pleases. The most important poin about this inquest, so far as the public is concerned, is th prevention of such accidents in the future. It is the rule i most breweries—and in this brewery at Rhymney it is th rule with regard to the larger vats—to have a man place outside as a watch and to lower a lighted candle befor entering the vat. But is that rule always put into practice And surely the fact that a candle will burn in an atmo sphere containing 10 per cent. or 12 per cent. of carbo dioxide, whereas death will occur in one containing onl 4 per cent. or 5 per cent., makes the candle test no sufficien guarantee of the fitness of an atmosphere for respiratio The jury brought in a verdict of "Death by misadventure, and added a rider that more stringent precautions ought t be taken to test the purity of the air and that a watch shoul always be placed outside the vat.

Rhymney, Mon.

SUPRAPUBIC CYSTOTOMY PAINLESSLY PERFORME AFTER THE HYPODERMIC INJECTION OF EUCAINE.

BY T. VINCENT JACKSON.

ON Feb. 20th, 1900, I had to perform suprapubi cystotomy in the case of a man, aged 50 years. Th reasons for this operation need not be stated. As th general condition of the patient seemed unfavourable to th employment of a systemic anæsthetic I determined to tes the efficacy of local anæsthesia. The man's face was covere by a towel and in two or three points over the line of th incision which would have to be made above the pubo 40 minims in all of a 7½ per cent. solution of hydrochlorid of eucaine (equal to two and two-third grains of the drug were hypodermically injected into the tissues. A shor period was allowed to elapse and then the operation wa commenced and was finished by the insertion of three dee and two superficial catgut sutures, which when tied brough the soft parts together above a drainage-tube placed withi the bladder, and the dressings were then applied. Durin the operation the forefinger of an assistant was passed int the rectum to raise up the floor of the bladder. When al was completed I removed the towel from the man's fac and asked him if he had felt anything, to which he replied "I felt a finger in the fundament."

I publish this case as evidence of the great value whic the employment hypodermically of a solution of eucain may be in the performance of a major operation which ca be rapidly executed.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv. Proœmium.

ST. GEORGE'S HOSPITAL.

TWO INTERESTING CASES OF HERNIA.

(Under the care of Mr. G. R. TURNER.)

CASE 1. *Femoral hernia in a boy, aged six years.*—The patient was admitted into St. George's Hospital with a swelling of the size of a pigeon's egg in the left groin, seemingly reducible into the abdominal cavity and apparently with some slight impulse on coughing. There was enlargement of the inguinal glands above and below Poupart's ligament and the child had obviously been circumcised not long ago. Both testicles were in the scrotum; the hernial swelling was said to be increasing in size. The hernia on operation proved to be of the femoral variety containing omentum. A radical cure was performed, a flap from the pectineus muscle being utilised in the way that Mr. Watson Cheyne has suggested. The boy made an uninterrupted recovery.

CASE 2. *Double femoral hernia in a man.*—The patient, a labourer, aged 46 years, was admitted into St. George's Hospital on May 31st, 1893. He stated that he had had a reducible lump in the fold of the left groin for 12 months. This had increased in size somewhat suddenly of late. He was subject to bronchitis in the winter months, but otherwise he had enjoyed good health. He had neither lost nor gained flesh recently. He had never worn a truss. There was a smaller swelling in the right groin. On admission the patient was found to have a femoral hernia of about the size of a Tangerine orange which was readily reducible on the left side. He had a smaller right femoral hernia and both inguinal rings although unoccupied by hernia were very capacious. On June 3rd Mr. Turner operated on the left side, doing a radical cure of the femoral hernia and suturing the inguinal ring with kangaroo tendon at the same time. Three weeks later he did the same on the right side. The femoral herniæ on both sides were omental; no gut was down on the left side at the time of operation, although previously this had probably been the case. The patient was discharged wearing a double truss large enough to support both inguinal and femoral rings.

Remarks by Mr. TURNER.—Femoral hernia in a boy, aged six years is sufficiently rare to be worthy of record. Double femoral hernia in an adult man is not often seen. It was associated in the case recorded above with dilatation of the inguinal rings, although no hernia was present in these situations. It is curious that on both sides the hernia should have selected the crural canals when an easy inguinal route was open to them. As a general rule after the operation for radical cure of a hernia I do not advocate the wearing of a truss, but in this case the rings were alone dealt with and the truss is worn as a matter of prevention of possible hernia in the future.

GREAT YARMOUTH GENERAL HOSPITAL.

A CASE OF SUPPURATIVE OTITIS; MASTOID DISEASE; CEREBRAL ABSCESS; NECROPSY.

(Under the care of Dr. HENRY BLAKE.)

FOR the notes of the case we are indebted to Dr. Alexander Goodall, house surgeon.

A youth, aged 17 years, was admitted into Great Yarmouth General Hospital on Sept. 22nd, 1899, under the care of Dr. Blake. The patient complained of pain and discharge from the left ear of about three weeks' duration. His family history was good, his home surroundings were comfortable, and he had not suffered from any previous illness of importance. His intelligence was not of a high order and it was difficult to get an account of the onset of his illness. On admission the temperature was 100·4° F. There was a good deal of purulent discharge from the left ear and a small polypus could be seen growing from the posterior wall of the meatus. There was no tenderness over the mastoid. The pulse was 72 per minute and in other respects the patient seemed to be in good health.

The ear was douched with boric lotion and insufflated with iodoform. Chromic acid was applied to the polypus. On Sept. 25th the temperature rose to 104·5°, but after cold sponging it fell to 100°. For the next three weeks the temperature was very irregular, ranging from 98·4° to 103°, but the general condition seemed to improve and operation was deferred. On Oct. 2nd the patient vomited and he began to suffer from severe paroxysmal headaches. On the 16th the mastoid was trephined and a few drops of pus escaped. A communication was made between the mastoid antrum and the meatus. The temperature, however, remained irregular, ranging from 100° in the morning to 103° in the evening, and on the 24th the patient had a rigor. On the 28th the mastoid opening was enlarged and some bony detritus was cleared out. On the 30th the temperature rose to 102°. There were swelling and tenderness along the line of the internal jugular. On the next day the swelling and tenderness had extended along the line of the subclavian vein. Carbolic fomentations were applied and in two days these symptoms had subsided. On Nov. 1st, and again on the 3rd and the 5th, the patient vomited. On Nov. 1st the temperature fell to 97°, but on the 2nd it rose to 102°. The patient was now rather drowsy and his cerebral processes became very slow. On the morning of the 6th the temperature was normal and the pulse rate was 60. At 10 A.M. the temperature fell to 96° and the pulse rate to 48. There were slight paresis of the right facial nerve and a slight tendency to ptosis of the left eyelid and the left pupil was dilated. The fundus oculi looked healthy. In the evening Dr. Blake trephined over the temporo-sphenoidal lobe, entering the trephine at a point about one and a quarter inches behind and above the centre of the external auditory meatus. An incision was made in the dura mater and an exploring needle was inserted into the temporo-sphenoidal lobe. Pus was at once found and about one ounce escaped. The opening was enlarged with sinus forceps and a rubber tube was inserted and stitched to the scalp. On the next morning the temperature was 97° and the pulse was 64. To ensure better drainage the rubber tube was replaced by a silver cannula. In the evening the temperature had risen to 102° and the pulse-rate to 84. The following morning the temperature was 101° but it gradually rose to 105·2° and the patient died in the afternoon.

Necropsy.—A post-mortem examination was made on the following day. There was a small ragged opening about the middle of the inferior temporo-sphenoidal convolution where the tube had been inserted and around the opening there was an area of about a square inch where the brain substance was very thin and friable. On cutting into the brain an abscess containing a quantity of pus was found in the temporo-sphenoidal lobe. The cavity had a diameter of one and three-quarter inches and projected into the descending horn of the left lateral ventricle. The abscess cavity was lined by a pyogenic membrane one sixteenth of an inch in thickness, which was very easily detachable from the brain substance. There was no thrombosis of either the internal jugular vein or the lateral sinus and there was no indication of meningitis.

Remarks by Dr GOODALL.—The diagnosis when the patient first came under observation was septic absorption from purulent otitis and it was only the continuation of the symptoms after douching, &c., that indicated mastoid disease. After the second operation there was reason to believe that there was venous thrombosis, and it was only the rapid extension of the condition that prevented operation. Subsequent events proved the decision to defer operation to have been fortunate. The most interesting feature of the case was the fact that the abscess, which had a thick pyogenic membrane, must have existed for weeks before it gave rise to any symptoms. The patient's mental processes were certainly slow, but it so happened that his sister, who was in hospital at the same time suffering from chlorosis, showed much the same peculiarity. It was, therefore, impossible to determine when the slow cerebration became pathological. Definite symptoms of brain abscess only showed themselves two days before the boy died. I am indebted to Dr. Blake for his kindness in allowing me to publish the case.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Rupture of the Œsophagus caused by Vomiting.—Sarcoma of the Gastro-hepatic Omentum.

A MEETING of this society was held on March 27th, Dr. F. W. PAVY, the President, being in the chair.

Dr. R. L. BOWLES and Mr. G. R. TURNER communicated a paper on a case of Rupture of the Œsophagus caused by Vomiting, together with a table of 16 other cases hitherto recorded. The patient was a woman, aged 62 years, who, after taking over-night a pill of aloes and rhubarb, which freely purged her, was sick on taking some milk. She vomited four or five times and still feeling ill took a tumblerful of salt-and-water "to clear the stomach." The vomiting caused by this was followed by collapse of an alarming nature and epigastric pain, and she complained of agonising pain on swallowing. All vomiting ceased after the sudden onset of the pain and collapse. Under the influence of hypodermic injection of morphia her condition somewhat improved. Ausoultation was difficult, but as far as could be ascertained the cardiac sounds were absent and the chest was hyper-resonant. Emphysema of the neck, soon extending to the face, appeared some hours before her death, which occurred 22½ hours from the commencement of the attack. The post-mortem examination showed emphysema of the chest and neck, chiefly on the left side, and left pneumothorax, and one and a half inches above the diaphragm there was a longitudinal rupture of the œsophagus which was otherwise healthy. Some remarks were made on the diagnosis of this form of accident from perforation of the stomach, the duodenum, rupture of an aneurysm, angina pectoris, severe colic, and irritant poisoning. With reference to the surgical treatment allusion was made to the possibility of exposing the œsophagus in the posterior mediastinum without injury to any important viscus. Drainage of the posterior mediastinum and suture of the rupture were regarded as feasible and an attempt at such treatment was fully justified in what was otherwise a necessarily fatal injury. The literature on the subject was analysed and 16 other cases were tabulated. This class of injury, though rare, was not so rare as was usually supposed. It was an accident that might be overlooked and sometimes confused with post-mortem softening. —Dr. CYRIL OGLE had made the necropsy on the case and regretted that the specimen had been lost. There was no doubt that the rent had occurred before death. The emphysema and pneumothorax were beyond doubt. As to the œsophageal rent, there were no signs of any disease in the gullet; it was softened a little in the lower part, but that was due to post-mortem softening.—Dr. H. D. ROLLESTON referred to the very exceptional character of the accident. In the forty-fifth volume of Transactions, under the heading Peri-œsophageal Abscess, he had published an example of rupture. The patient was a coachman, aged 56 years. The rupture had occurred when he was bending to clean a carriage and he died 48 hours afterwards. The posterior mediastinum contained the cavity of an abscess. He referred to the definite situation in which the rupture was always found. It was always in the lower third. This was strange because the weakest part was found where the pharynx joined the œsophagus. Possibly this situation was explained by the lower third being composed of smooth muscular tissue only, and here it was firmly fixed to the diaphragm. He believed that rupture was probably preceded by a small ulceration and this was most frequently found in the lower third. The rupture might destroy the evidence of ulceration.—Mr. STANLEY BOYD mentioned a case recorded by Tündler[1] of a lad, aged 17 years, suffering from a contused wound of the arm with septic complications. On the fourth day vomiting set in and a transverse tear of the œsophagus took place, the contents of the stomach being extravasated into the pleura. He also referred to two cases which he (Mr. Boyd) had recorded in the Transactions of the Pathological Society of London, in which, although a committee were of the opinion that the lesion was due to post-mortem softening, he still believed the apertures were due to rupture. There were clinical grounds in support of this view.—Mr. THOMAS BRYANT referred to the rarity of such cases. He had met with three or four cases due to external injury, but this was, of course, a different condition. He mentioned a case which had given rise to difficulty at the time, but which in the light of the cases mentioned by Dr. Bowles [illegible] Turner was probably one of rupture of the gullet. The patient was an imbecile who while in good health was suddenly seized with severe vomiting and collapse. She was thought to have swallowed a piece of wood, but no impediment could be detected on passing a bougie. After death nothing was found excepting a vertical rupture in the lower one-third of the gullet. The question was raised whether it had been done by the instrument, but he had no doubt it was a case of the kind under discussion.—Dr. R. L. BOWLES, in replying, mentioned that the pulse of the patient was only 50 and the arterial tension, in spite of the collapse, was high. This was probably explained by irritation of the vagus nerves. The position of the rupture in the lower one-third was, he believed, partially explained by this being the narrowest portion of the tube. In some experiments which he and Mr. Turner had performed, rupture of the gullet always occurred vertically; he believed that leaden pipes when bursting always split longitudinally. He thought the gullet was not examined as often as it should be post mortem. —Mr. G. R. TURNER was inclined to agree with Dr. Rolleston in his explanation of how the rupture occurred, but could not believe that previous ulceration was necessary. He had been surprised how easily the healthy gullet ruptured in his experiments. He agreed that Mr. Stanley Boyd's cases were probably rupture rather than post-mortem softening. He was inclined to think that the accident was a little more common as a cause of sudden death than was generally believed. In regard to possible surgical treatment, since there was already pneumothorax it was not necessary to avoid the pleura.

Mr. A. PEARCE GOULD read a paper on a case of Sarcomatous Tumour of the Gastro-hepatic Omentum removed by Operation, with remarks on the Diagnosis of such Tumours. The patient was a man, 38 years of age, who came under his care in October, 1895, for a large solid abdominal tumour which had been noticed for about 12 months. When operated upon it was found to occupy the gastro-hepatic omentum and the stomach was displaced into the pelvis. The tumour, which weighed 21 lb., was enucleated from the omentum. Microscopic examination showed it to be a spindle-celled sarcoma with extensive hæmorrhages into its tissue. The patient, who was brought before the society, made a good recovery and had remained well since without sign of recurrence, a period of four and a half years. Mr. Gould drew attention:—1. To the extreme rarity of primary tumours in the gastro-hepatic omentum. He had found a record of only one other case. 2. To the means of diagnosing a tumour in this situation. The chief clinical feature about tumours in the small omentum depended on the fact that the stomach was pushed downwards and therefore the usual epigastric resonance was wanting. 3. To the very great elongation and displacement of important structures which occurred without serious symptoms and was recovered from without ill effect. 4. To the long period of freedom from recurrence after removal of a sarcoma of apparently malignant character. The patient, the tumour, and a microscopic section of the latter were shown.—Mr. THOMAS BRYANT recalled a case in 1885 of a large abdominal tumour weighing 50 lb. occurring in a middle-aged man. It was non-lobulated and of slow growth. It was thought at first to be fluid. Considerable difficulty was experienced in making out its boundaries and origin; it turned out to be an enormous lipoma with very large veins. The needle used for puncturing it came out quite clean but covered with oil. This was one of the best evidences of a lipoma.—Mr. STANLEY BOYD referred to the difficulty in diagnosing the locality of such tumours. He mentioned the case of a youth, aged 20 years, who presented a tumour of the upper abdomen which pushed up the heart. It was very tense and rounded, like a hydatid of the left lobe of the liver. It moved on respiration, but not as a hydatid would. An exploratory operation was performed and it turned out to be a retro-peritoneal cyst. 70 ounces of red-brown fluid were drawn off, which digested starch and albumin, and which showed that it was a cyst of the pancreas. This tumour certainly obscured the stomach, yet it was not a tumour of the small omentum, so he could not agree with the statement that displacement of the stomach resonance was pathognomonic of tumours in the latter situation.—Mr. PEARCE GOULD, in reply, remarked that the case just referred to was somewhat unusual. All tumours of the small omentum must push down the stomach, and the resonance of that organ would not only be obscured but would re-appear below.

MEDICAL SOCIETY OF LONDON.

The Chemistry of Gout.

A MEETING of this society was held on March 26th, Dr. F. T. ROBERTS, the President, being in the chair.

Dr. A. P. LUFF read a paper on the Gelatinous form of Sodium Biurate and its bearing on the Treatment of Gout. It was, he said, now a universally admitted fact that the deposition of sodium biurate was intimately related to the gouty paroxysm. He strongly shared the view of the late Sir William Roberts that uric acid when first introduced into the blood existed solely as sodium quadriurate. It was, however, a very unstable body and soon changed into sodium biurate, which at first assumed the gelatinous modification; and this if not eliminated in the urine was slowly or rapidly (according to circumstances) changed into the almost insoluble crystalline form, which by its deposition in the tissues caused the gouty paroxysm. If this change from gelatinous to crystalline form could, be delayed the gouty attack could be delayed or postponed. He had for some time been studying the effects exerted by various drugs on the conversion of the biurate into the crystalline form. He had shown on previous occasions that the conversion was accelerated when the alkalinity of the blood was increased by means of sodium bicarbonate, whereas the conversion was delayed and diminished when potassium bicarbonate was used. He had now carried out a similar series of experiments the results of which showed: (1) that sodium salts considerably accelerated the conversion of the gelatinous biurate into the crystalline variety and that their employment in the treatment of gout was apparently not desirable; (2) that potassium salts delayed the conversion of the gelatinous biurate into the crystalline form and also that when the conversion was once started it was slowed by the presence of these salts; (3) that lithium salts, although they did not delay the initial conversion of the gelatinous biurate, yet when the conversion was once started it was slowed by the presence of these salts and especially by the lithium carbonate; (4) that piperazine did not delay the initial conversion of the gelatinous biurate and but slightly slowed the conversion when once started; and (5) that lysidine, although it delayed the conversion of the gelatinous biurate into the crystalline form, yet when the conversion was once started it had practically no effect in slowing it. From the results of these experiments it appeared that for the special purpose referred to in the treatment of gout the potassium salts were the most useful, that the lithium salts ranked next, and that piperazine and lysidine were not nearly so useful. These results were entirely in accord with his clinical experience. He did not for one moment wish to contend that the beneficial action of the salts of the alkali metals in the treatment of gout was to be solely gauged either by their solvent action on deposits of sodium biurate or by their inhibitory action on the conversion of the gelatinous biurates into the crystalline form. Undoubtedly many of them were extremely useful in the gouty state by their stimulating effect upon metabolism, by their remedial action upon the gastric and hepatic functions, by their diuretic action, and by diminishing the acidity of the urine. He feared that the purport of a paper published by him in THE LANCET of June 11th, 1898, had been somewhat misunderstood in this respect. He did not, however, question—still less deny—the utility of many of those drugs in the therapeutics of gout, but he wished to point out that the oft-repeated statement that most of these drugs were useful for their great solvent action on gouty deposits was a loose and erroneous statement which it would be wiser in future to avoid. Another important point demonstrated by his recent experiments was that the higher the alkalinity of the blood from the presence of sodium bicarbonate the more rapid and the more complete was the conversion of the soluble gelatinous biurate into the comparatively insoluble and crystalline forms. This point was of great interest, since he believed that the alkalinity of the blood of gouty patients was always higher than the normal alkalinity of blood. This view was opposed to the prevailing one that gout was associated with an "acid dyscrasia." This latter opinion, however, *so far as he could* ascertain, was a pure assumption and had apparently never been based upon any actual determinations of the alkalinity of the blood of gouty individuals. It received its first shock five years ago when Klemperer showed by actual determinations of the blood of gouty subjects that the alkalinity was not below that of healthy blood. He had since made a number of determinations of the alkalinity of the blood of healthy and gouty individuals with the result that the alkalinity was higher than the average alkalinity of the blood of healthy individuals. The alkalinity of the blood of healthy adults varied from 0·161 to 0·185 per cent. of sodium carbonate, with an average of 0·167 per cent. The alkalinity of the blood of gouty patients varied from 0·193 to 0·251 per cent., with an average of 0·217 per cent., which was nearly one-third higher than that of normal blood. Since this increased alkalinity of the blood was due to a higher proportion of sodium carbonate or bicarbonate, and since these substances accelerated the conversion of the gelatinous biurate into the crystalline variety, and therefore the precipitation of the latter, it was intelligible why such blood was prone to hasten and to augment the formation of gouty deposits. The inference was, therefore, that this increased alkalinity determined the gouty paroxysm.

Dr. WILLIAM BAIN (Harrogate) read a paper on the Action of Various Drugs and Diets on the Excretion of Nitrogen in Gout. The object of his series of observations was to determine if possible the variations in nitrogenous elimination occurring in a case of gout under ordinary conditions and to note the effect of different diets and certain drugs on such variations. For this purpose urea, uric acid, the alloxur bases, and ammonia were estimated in the urea to serve as a measure of the total nitrogenous changes; the uric acid and alloxur bases to serve as a possible sign of modified production of these bodies; and the ammonia as an indication of the general amount of inorganic acid dealt with during the day's metabolism. With regard to the origin of uric acid there were two alleged sources: (1) it might be a derivative of the alloxur bases combined within the molecule of the nucleoproteid of cells or similar substances in the food; and (2) it might be produced by synthetic processes in the liver or elsewhere from simple nitrogenous compounds, such as ammonia. The patient, a well-built man, aged 65 years, was admitted into the Leeds General Infirmary in November, 1899, under the care of Dr. A. G. Barrs (to whom Dr. Bain was indebted for the opportunity of investigating the case). The family and previous histories were unimportant. The patient had been suffering from severe and constantly-recurring attacks of gout for five years and there were very obvious gouty changes in the hands, feet, and other joints. He had no pain in them excepting during the inflammatory attacks. The large amount of deposit in a short time was specially remarkable. The abstemious habits of the patient and the absence of gout in the family history were also noteworthy. After describing the methods employed in estimating the various substances Dr. Bain exhibited his results in the form of a table. After sodium salicylate there was only a slight increase in the uric acid. Under guaiacum uric acid was markedly increased. It was thought that this drug probably acted on the uric acid stored in the body rather than by increased production. Iodide of potassium caused an increase in the urea and uric acid. Vegetable diet increased the uric acid. Dr. Bain also made reference to the experiments of Minkowski which added much interest to his estimation of the alloxur bases. This observer had administered adenin to four dogs in doses varying from a quarter to two grains several times a day. After two grains vomiting ensued and the other symptoms noted were violent action of the heart, a heaving pulse, with an increase in blood-pressure. The urine contained leucocytes, albumin, casts, and epithelial cells. Three of the animals were killed about the fourth day and the other one died. Post mortem crystals of biurate were found deposited in the renal tubules. It was an interesting fact that this train of symptoms with deposition of biurate could be experimentally induced by one of the alloxur bases, and it suggested that one or more of them might be a factor in the evolution of gout. Uric acid, on the other hand, had not been shown by experiment to produce any such symptoms. With advancing knowledge it was possible that uric acid gated to a secondary [illegible] the causation of gout. It was to be regretted that this line of research had not been extended and it was unfortunate that pure adenin was almost impossible to obtain. Apart from xanthin the amount of alloxur bases appearing in the urine was so exceedingly small that their separate estimation was a matter of great difficulty. Dr. Bain suggested the possibility that the retention of adenin within the system might determine the deposition of biurate in the tissues.

Dr. A. E. SANSOM confessed that he was still in a maze of doubt as to the pathology of gout, though experiments seemed to be elucidating some of the problems. There was no doubt that the deposit of urates was the cause of a gouty attack; but why should it, he asked, be afterwards got rid of in some cases but not in others? The absence of pain, too, in some cases was inexplicable. It seemed to him doubtful whether those violent and destructive paroxysms of acute gout sometimes observed could be explained wholly and solely by sodium biurate. Surely there must be something that was associated with it which prevented metabolism. The subject of treatment also was beset with difficulty. If sodium salts promoted and potash salts delayed deposition why was it that they got such good results from the two together? Piperazin in his experience did seem to do good in some cases. Laboratory experiments were very useful, but they were still a long way off the truth.

The PRESIDENT congratulated Dr. Luff on his welcome and interesting researches. He had never thought very much of piperazin or lysidin in the treatment of gout and he had mostly come back to the potash salts or a combination of potash and soda. Dr. Bain's case was an interesting one and he remembered to have met with a case resembling this in the extreme gouty development without anything to account for it, for the patient was both a teetotaler and a vegetarian.

Dr. A. P. LUFF, in reply, thought that the disappearance of the deposit in some cases and not in others depended upon the alkalinity of the blood. If this was high then the blood could not remove the deposits. The presence or absence of pain in different cases depended, he believed, upon the rapidity of deposition. It was the suddenness of the deposition which caused the pain. Referring to the necrosis of certain tissues he doubted whether such a process occurred in cases of true gout. He had never seen necrosis of cartilages in true gout, and he thought it possible that the alleged cases were rheumatoid arthritis on which acute gout had supervened. Dr. Bain's case had been very carefully investigated. He would like to know what were the relative lengths of time for the administration of the different substances. He thought that in so many experiments in one patient the gouty state must have been in different phases at different times. The fact that guaiacum eliminated uric acid was quite in keeping with his experience and that of Sir Alfred Garrod. Given in the form of resin it was certainly a prophylactic.

Dr. BAIN, in reply, mentioned the doses and duration of the administration of the different drugs. There was an interval of three days between each, but the patient began by being put on a fixed diet for nine days. He thought the question of pain would depend upon the structures that were involved. As to the necrotic changes he quite agreed with Dr. Luff. Dr. Chalmers Watson had found in chronic gout a myelocyte which was not to be found in normal blood, but Dr. Bain had not found this in one case which he had examined. He quite agreed with Dr. Sansom that there must be something besides the biurate to produce gout and he had suggested that it might be adenin. The marked effect which this had had upon the blood-pressure and the occurrence of uric acid in the kidneys of Minkowski's dogs were arguments in favour of this view.

CLINICAL SOCIETY OF LONDON.

A Case of Dermoid Cyst within the Spinal Canal.—Reduction of the Deformity of Spinal Caries by Manual Rectification.

A MEETING of this society was held on March 23rd, Sir R. DOUGLAS POWELL, Bart., President, being in the chair.

Dr. W. HALE WHITE and Mr. A. D. FRIPP communicated a paper on a case of Dermoid Tumour growing within the Spinal Canal in which an attempt was made to remove the growth. The patient was a man, aged 26 years, who had been suffering from a very chronic form of Hodgkin's disease. He was first seen by Dr. Hale White and Mr. Fripp with Mr. A. F. Wilson at the end of March, 1899. In the middle of January, 1899, the patient began to complain of loss of power in the legs. By the end of March there was complete paraplegia without muscular wasting. The breathing was almost entirely diaphragmatic, the right hand was much stronger than the left, and all forms of sensation were lost up to the level of the nipples; there was no hyperæsthetic zone; there was severe pain shooting down both intercosto-humeral nerves and round the chest along the second intercostal nerves, the lower limbs were rigid, the knee-jerks and plantar reflexes were exaggerated, and there was great superficial tenderness over the second, third, and fourth dorsal spine. There was incontinence of urine with cystitis and obstinate constipation and great distension of the abdomen. The pulse was 120 and the temperature generally was about 101° F. There were no signs pointing to caries and aneurysm. The diagnosis was that there was some collection of fluid or a new growth within the spinal canal irritating the second dorsal nerve and compressing the cord below it. There was no evidence that this was syphilitic or that it was malignant. An exploratory laminectomy was performed, the second, third, and fourth dorsal arches being removed. A grey tumour situated upon the outer surface of the dura mater was exposed, which reached out of sight both above and below. Pieces of the growth were snipped away. The patient quickly rallied from the operation and the wound healed by first intention. The tumour proved on microscopical examination to be a dermoid cyst. The patient was seen again by Dr. Hale White and Mr. Fripp eight weeks later. The pulse and the temperature were normal. There was slight and occasional voluntary movement in the legs. The exaggeration of the knee-jerks was less and the rigidity had disappeared. There was almost complete return of all forms of sensation down to the groins, but no improvement in the lower extremities. The radiating pains had disappeared. The chest moved better. The cystitis and incontinence had disappeared and the constipation and abdominal distension were less. There was a large bedsore on the sacrum and another on the buttock. Considerable as had been the improvement it appeared to Dr. Hale White and Mr. Fripp that as much of the tumour had been left behind, and as the pressure symptoms were far from completely relieved, the only chance of benefiting the patient lay in a further attempt at complete removal. A second operation was performed. A large mass of the tumour was found to have grown backwards through the gap in the spinal canal made at the first operation. The first, fifth, and sixth dorsal laminæ were removed, but still no limit could be seen to the growth. The patient rallied well but sank again eight hours after the operation.—The PRESIDENT remarked that the case was of interest as bearing on the question how far interference was justifiable in cases of this kind.—In reply to the President, Dr. HALE WHITE said that the case was unique as regarded the nature, though not as regarded the position, of the tumour. Cases of dermoid cysts had been recorded in the middle line between the skin and the spines, but not within the spinal canal.

Mr. ROBERT JONES (Liverpool) and Mr. A. H. TUBBY communicated a paper on the Reduction of the Deformity of Spinal Caries, based on 99 cases of angular deformity from Pott's disease treated by Manual Rectification, including results of the 25 cases which had been brought before Clinical Society of London in November, 1897. In this series of 25 cases the following results had been obtain five patients had died, four had discontinued treatment, were alive, well, and able to walk, and one was still cumbent and sickly. As to the causes of death, one di four days after the operation, but post mortem no abnormali was found beyond some enlarged mesenteric gland one died from tabes mesenterica 15 months after th operation; one died from pulmonary tuberculosis 16 month after the last stretching, one from intestinal obstructio twelve months after, and one from diphtheria. Billroth, Menzel, Jaffé, and Mohr estimated the death-rate from Pott's disease to be 25 per cent., the death-rate of the series observed by Mr. Jones and Mr. Tubby being only 12 per cent. Four of the cases developed abscesses, of which two healed and one patient became paraplegic eight months after the operation, but had since recovered. Five of the 25 patients recovered from paraplegia as the immediate result of the operation, recurrence taking place in one case. In five cases the curvature was practically obliterated and remained so with a spinal support, and the curve was much improved in ten of the cases. In a parallel series of n rectified cases three patients had died from tubercle, f had developed abscesses (two of them healing), four had become paraplegic with two recoveries, and in seven the deformity was very marked. Mr. Jones and Mr. Tubby then brought forward a series of 74 cases subsequently operated on. Of these seven patients had died, 29 were walking, 28 were recumbent, and 10 had discontinued treatment. As to the causes of death, one patient died from empyema four weeks after operation; one died from general tuberculosis thirteen days after operation, and another two years after; one died from pulmonary phthisis eighteen months later and one from pneumonia two years after; one died from exhaustion; and one died six months after reduction for paraplegia, without relief, from diarrhœa. Three patients were operated upon while abscess was present and 13 developed abscesses subsequently, of which nine had healed. Seven patients had recovered from paraplegia, or the condition had been relieved and had remained so. In 16 the curvature had either not improved or had become worse, but not necessarily as the result of the operation. Mr. Jones and Mr. Tubby deprecated the employment of much force, their plan having been to proceed by stages with an interval of a month between each attempt. They laid it down that the after-treatment should not be less than three years. Their conclusions were as follows: (1) that danger to life was not great; (2) that far from inducing paraplegia the operation was actually a curative measure; (3) that abscess formation was, if anything, less frequent; (4) that the risk of disseminating tubercle was a negligible quantity; and (5) that there was no risk of a flail-like spine The contra-indications were: (1) cervical and high dorsal curves, unless associated with paralysis; (2) ankylosed spines; (3) large and angular deformities; (4) evidences of tubercle elsewhere; (5) in children under two years of age and in adults over 22 years; and (6) the presence of abscess unless there were paraplegia. They advised the operation only when the spine was yielding and in comparatively strong children free from abscess and tubercle. They pointed out that the operation was not to obliterate all the prominence, but to give as erect a position as possible. Lastly, they urged that cases for operation must be selected with great care, that personal attention to the patients must be unremitting, and that fresh air was an all-important factor in the after-treatment. They exhibited a selection of the first series of 25 cases showing the actual results.—The PRESIDENT observed that whatever they might think of the ultimate results of the treatment the facts brought before them must materially alter many of their present views. He asked whether albuminuria due to myeloid disease had disappeared when the surgical deformity was remedied —Mr. J. JACKSON CLARKE said that he had followed the revival of forcible correction of deformity in spinal disease with great interest. He believed that he was the first surgeon to perform the operation in London. In order to understand the results obtained in the cases before the society it was necessary to consider the methods previously employed. Mr. Tubby had put it on record that up to 1896 he had chiefly used corsets of plaster or of felt. Mr. Clarke had found the results of such appliances to be very disappointing. Mr. Jones had chiefly employed Thomas's cuirass which was also used in the after-treatment of many of the cases before the meeting. This cuirass, which exerted a leverage action on the spine, had certain defects, though it was, in Mr. Clarke's opinion, better than any other corset It did not lend itself to periodical re-adjustment and thus was no help to gradual correction of deformity; it did not provide for alterations required by the growth of the patient, and again it did not readily lend itself to the addition of a head-piece needed in high dorsal and cervical cases. By the use of an antero-superior support which did not possess these disadvantages Mr. Clarke had obtained results which he believed compared very favourably with those seen in the cases now shown by the authors of the paper. Thus in some cases of lumbar disease the deformity had been obliterated; in other cases it had been considerably diminished. These results had been obtained sometimes after a period of rest in bed or on the couch, but more often with ambulance treatment throughout. The educational aspects of spinal cases had to be considered and a method of treatment that allowed a patient to be taught at home or to go to school was, other things being equal, to be preferred to one that demanded two or three years of fixation upon an apparatus in the dorsal recumbent position. The death-rate of 25 per cent. quoted from Billroth as being observed in cases treated without forcible extension was far too high. Even that of 12 per cent. observed by Mr. Jones and Mr. Tubby in the cases which they had operated on was distinctly high, being above that observed by Mr. Clarke in cases treated in London. It was to be noted that in more than one of the cases in the paper no real diminution of deformity had been obtained, and as regarded the future of the patients there was no proof that as soon as the apparatus was left off deformity would not return as the patient grew up owing to damage to the epiphyseal discs. The many contra-indications pointed out which would have to be observed in deciding to perform forcible rectification approximated closely to Mr. Clarke's own views, which were to the effect that this operation was only called for in exceptional cases. The chief indication was a paraplegia that had resisted a patient trial of gentler means.—Mr. RICHARD BARWELL questioned whether the good done was as great as they were asked to believe, and he doubted whether there had been actual straightening in many of the cases of the angular curve. On the whole he did not think that the results were better than would be obtained in three years by other methods of treatment. He observed that in the case of a child, who was said to have had paraplegia, the child was under two years of age at the time and possibly was unable to walk; moreover the mother said that the child had been able to move his legs. He pointed out that by lifting the patient by the arms and watching the angle it was easy to see whether the ulcer of the bones had healed. On the whole he thought the results were somewhat disappointing.—Mr. BERNARD ROTH said that since seeing these cases he thought there was more in the treatment than he had imagined, but he would like to see the cases a year after all instruments had been left off.—Dr. E. PERCY PATON asked how long the patients had remained in hospital under treatment and he pointed out that prolonged recumbency in the homes of the poor could not be desirable.—Mr. HOWARD MARSH commended the authors of the paper for the vast amount of patience and labour which they had devoted to the subject. They must, however, all feel that the subject had not been thoroughly threshed out though many interesting points had been raised, and he thought the question was one that might advantageously be referred to a committee for investigation and report. He was tempted to raise the question whether the conclusions arrived at by Mr. Jones and Mr. Tubby were justified by the facts which they had brought forward. He challenged the estimate of 25 per cent. as the probable death-rate from Pott's disease. He himself would put it at 5 or 6 per cent. He pointed out that paraplegia was equally recovered from under other methods of treatment, and he concurred in the view that the correction of the deformity was often more apparent than real —Mr. BERNARD ROTH seconded the reference to a committee, and some discussion ensued as to the scope of the reference and the way in which the inquiry could be carried out. Ultimately the proposal to nominate a committee was agreed to, the precise terms of the reference to be submitted to the council —Mr TUBBY, in reply, said that he thought it would be conceded that they had done their best to fulfil their pledge of two years ago to follow up those cases. He pointed out that they did not insist so much upon the value of the operation in remedying the curve. With reference to albuminuria he said that it disappeared when the abscess ceased discharging and no patient had died from lardaceous disease. He did not believe that equally good results could be obtained with instruments. In reply to Mr. BARWELL he said that the child stated to have had paraplegia had the lower limbs rigid with exaggerated reflexes and could not walk. He added that the labour, difficulty, and anxiety entailed by the endeavour to afford the society such a demonstration of results as that before them were very great, and he did not think that they could in any way manage to approve of a committee being sent about the country to inspect their cases, but the committee would, of course, be welcome to examine the records.

CHELSEA CLINICAL SOCIETY.

The Treatment of Rheumatism.

THE adjourned meeting of this society from March 13th was held in the Parish Hall, Pavilion road, Chelsea, on March 20th, Mr. FOSTER PALMER being in the chair.

The CHAIRMAN said that at the last meeting the Treatment of Rheumatism which they principally heard about, and ised by those present, was treatment. The causation which found most favour, although not yet actually proved, was the bacterial theory of origin. Until they knew for certain whether rheumatism was a bacterial disease or not their treatment must be more or less empirical and unscientific. He then called upon Dr. Pye-Smith to continue the discussion.

Dr. **PYE-SMITH** said the first thing they had to be sure about was that they were talking about the same thing. He began by saying what he understood when he spoke of rheumatism. He meant rheumatic fever and nothing else. He held that there was no such thing as chronic rheumatism. Acute and sub-acute rheumatism were one and the same thing. No doubt there were different forms that it assumed; in a child rheumatism took a different form to that seen in the adult, but it was all the same affection. He did not admit chronic rheumatism as having anything to do with rheumatic fever, nor had osteo-arthritis as it was called, or rheumatic gout, or arthritis deformans, or gonorrhœal synovitis, or gout, or pyæmia anything to do with rheumatism. That he onsidered was what they meant when they talked of the reatment and prevention of rheumatism. At present they ust define rheumatism by its clinical features which were ear and distinct; the multiple affection of the joints, the ansient synovitis, the fever, the comparatively short course, e tendency to recurrence, and, above all, the liability the heart to be affected, formed the clinical picture ich had been recognised since Sydenham. He thought y ought to keep strictly to that for their definition. ether rheumatism was due to a chemical poison or not not been discovered. It was certainly not due to lactic l or to uric acid; he ventured to say dogmatically that e was no evidence to support these hypotheses. Their rman had spoken of the view of the day that rheumatism d turn out to be due to a bacterium, but till it did turn, o be so surely the less they said about it the better. e was no benefit in anticipating in this manner. Passing e treatment of the disease he said they might be well led with the great progress made in the last 30 years. of them remembered what rheumatism was like in the before the salicylic treatment. It had been robbed of features of pain and distress—the very appearance patient was totally different. Formerly the very s on the patient's face showed at once what he was g from. Those who had seen rheumatic fever treated eding in Paris *coup sur coup* till the patient was d knew what mischief could be done in that way, and e treatments for rheumatic fever that he had seen was decidedly the worst. Rheumatic fever treated non juice in large doses was ill-treated and with it was inefficiently treated. The treatment with vas more intelligent and he remembered asking a f patients in regard to the discomfort caused and e equally divided as to the pain. The revolution ne into their practice when salicylic treatment was d had made rheumatism a different disease. What points they were still unsatisfied about? First, it iminished the mortality. He collected 400 cases ame hospital before the salicin treatment with 15 he number was larger than was really the case, d from an epileptic fit, one from an excessive dose , another was a case of strangulated hernia, and hs due to rheumatism they were from rheumatic ns, hyperpyrexia, pneumonia with pleurisy, heart previous rheumatism, so that the actual deaths c fever were very small. The apothecary at the pital was in the habit of saying to them, "Since you young gentlemen have begun to treat rheumatism the patients have begun to die." Dr. Donald Hood believed there was something in that, but no one could doubt the efficacy of the salicylate treatment in relieving pain. Some of them must have seen cases in which the salicylate treatment did not act favourably; the first patient he treated suffered from vomiting, diarrhœa, and hæmorrhage and that had been noted not infrequently. 12 cases had been collected in which hæmorrhage occurred not only from the kidneys but in the retina and he thought pretty clearly from the use of salicylic acid. They were familiar with the unpleasant consequences of the drug, the buzzing in the ears, the headache, and so on, but perhaps the most important thing in many ways was its effect on the heart. In cases where the pulse was good, with salicylates the pulse may become irregular and slow. Though the treatment was not an unmixed benefit still those effects might be prevented by giving ammonia or brandy, and if they bore in mind the the depressing effect on the heart—he referred to the undiseased heart—they could prevent it. Did the salicylate treatment diminish the liability to relapses? One of the most painful experiences was to see a patient have a after passing through the first attack without the heart being affected and have the heart suffer in the second attack. They would be glad if some means could be found to prevent that happening. He did not think tendency to relapse had been much altered by the salicylic treatment nor could they say that recurrences had been prevented, for rheumatism was one of the diseases that could occur again. From the general impression of the cases they saw they could say that on the whole the more severe a case was the more often the heart was affected. In children a slight attack with scarcely any synovitis might very seriously affect the heart; in adults the mild attacks were less often accompanied with cardiac disease; and in severe cases they expected to find a murmur and they were seldom disappointed. The fact that salicylates shortened the period and the severity of the disease did something to prevent cardiac complication. In shortening or diminishing the possibility of relapse salicylate kept on in small doses had a certain effect, but a more important thing was to keep the patient in bed as long as they could, if possible for six weeks. The old treatment was patience and six weeks in bed, and now, though the patient was not in misery and suffered no discomfort, it would be well to compel the virgin heart cases to lie in bed for six weeks. Another point was not to allow them to take solid food; the longer they could be kept on milk and mild unstimulating food the better. He would say if he were a young man 25 years of age with his first attack of rheumatism and no murmur that he should like to be put to bed, with milk for diet, water to quench his thirst, and large doses of salicylate of soda at frequent intervals till the fever had gone and the pain had disappeared, the dose then to be diminished but the drug not to be discontinued; and if there was an irregular or failing pulse he would have brandy as the most appropriate remedy. If doubtful sign about the heart occurred he thought it was very questionable whether they had any immediate means of acting upon it or preventing it, but if Dr. Oaton was in his neighbourhood he would certainly invite him to try multiple blisters. The only possible harm would be to perhaps prevent ease of mind and temper, but he was prepared on Dr. Oaton's authority to believe that there would be some considerable advantage from it.

Dr. R. **OATON** (Liverpool) said he would like to confine his remarks to the second part of the special subjects for debate—namely, the special prophylaxis against rheumatic valvulitis. He wanted to mention two or three experiments which he had been trying for the last 19 years with regard to this particular subject which was one of the most important points in regard to rheumatism. If they could get rid of the heart complications they would have comparatively little anxiety about their patients. His ordinary habit of treating patients was to keep them in bed and wrap them in flannel from the neck to the feet in every case to prevent the possibility of chill. He ordered a light diet, absolutely excluding all nitrogenous foods except milk. He gave salicylates, which he called the most glorious boon to the rheumatic, and he also prescribed a certain amount of cholagogue. The patient lost his pain and fever within 12 or 24 hours and if the pain lingered in any joint he personally always if the pain was obstinate applied a few blisters to the joint which invariably relieved the pain, swelling, and stiffness at small discomfort to the patient. He had tried it on himself and on hundreds of patients and provided the blisters were made small enough the pain and discomfort were almost unnoted. He could say that from his own personal experience and from that of hundreds of people. There was a feeling in the profession that blisters necessarily caused pain, and of course the acreage of blisters used by our forefathers was such as to cause pain and discomfort. When he had treated a patient in the way he considered the next question was, Would his heart remain free from trouble or would they have the most dreaded complications to deal with? He had been watching cases of rheumatic fever daily for 25 years and had seen them occasionally in private practice. When he began medicine, believing in what he had been taught, he treated the rheumatism and trusted that the cardiac complication would not occur, and if it came he hoped that it would disappear. He was much interested in these cases and took the trouble to watch the patients who had recovered from their illness and traced them out, but he was sorry to say that the result was a painful and disappointing one. He found that the bruit which had developed itself in hospital and which they had recovered from before leaving terminated in a life-long cardiac disablement. He felt this so keenly that 19 years ago he set to work to read up the subject to see if any hints could be found to help in trying to get a method to prevent this involvement of the heart. Some recommended huge blisters, icebags, leeches, poultices, large doses of mercury, and in his despair he tried a variety of these for four years with unsatisfactory results. At length he hit upon the following method: first of all to keep the patient who had developed a bruit, not a hæmic or temporary or dilatation bruit, but a true valvulitis bruit, in the recumbent position for a great length of time, preventing him raising his head even, guarding him from all possible excitement, with the object, of course, of slowing as far as practicable the action of the heart and keeping down the blood-pressure and preventing the strong blood waves of high tension from injuring the swollen and softened valve cusps. He tried to do that, though it was difficult to get the patient to submit to it because he thought he was cured of his rheumatism and considered himself well. He only began to learn after some years of practising this method how enormously important the prolonged rest was. Then there was a second point: he was anxious to discover some method of influencing the heart itself. They knew there were certain nerves, certain cutaneous nerves, in special relation to the heart, the first, second, third, and fourth dorsal intercostal nerves. Those who had watched angina or cardiac inflammations knew how frequently these nerves were the exponents of the mischief that was going on. The heart was related to these nerves and he hoped it might be possible to send a stimulus through these afferent nerves. Experiments showed it was possible to influence the blood-vessels and it seemed likely that they might also use a stimulus applied to these nerves to increase and augment the reparative function of the vaso-motor and trophic nerves in the heart. He tried the experiment of using small blisters along these nerves, not over the præcordium—that had no relation to the heart, they might as well try blistering the leg as there—but it was along these four nerves which were specially related to the heart that for 15 years he had tried these blisters, of the size of a florin or less, one at a time, following each by a small poultice to keep up a gentle stimulation of these nerves. He had not had any complaint from women or children and he had never heard any expression of suffering. The third method he tried, beyond the rest and blistering, was the administration of sodium iodide or potassium iodide about from eight to ten grains three times daily. It was given in the hope that it might aid in the absorption of inflammatory products in the endocardium which filter their way into the cusps of the valve. It was hoped that while these inflammatory effusions were still unorganised that it might be possible to aid their removal. Once organisation had taken place the removal was in all probability hopeless. When once alteration and puckering had taken place all chance of the renovation of the valve was hopeless. At the very first if the affection could be attacked in the early stage while the inflammatory condition was not organised its absorption and removal might be secured. They would see that these were all mere theoretical ideas and they would ask what proof was there. He admitted they were theoretical, but they had a certain amount of reasonableness; certainly the first had, and perhaps the other two had. The evidence he could give was the evidence of results. He had had over 500 cases of acute rheumatism in the last 15 years and in a great many they had no cardiac complication—considerably under 20 per cent. The great difficulty in experimenting upon endocarditis was that the great majority of the cases in the hospital had the disease established on admission, and it was hard to say whether the case was *sufficiently recent to be benefited or not. Out of the* cases he mentioned 54 had the various phenomena of cardiac mischief on admission, but there seemed a chance that the disease was recent though he was not sure in all. Out of the 54 cases 34 went out with quite normal hearts without dyspnœa of any description. They were all urged to rest and avoid exertion for several months. He had watched these cases as far as he could. Some were sailors, some were servants, some therefore went far away, but many he had followed for months and for years, and in the great majority the heart had remained perfectly sound. The second class, however, were those who came in with perfectly normal hearts and in whom the evidences of valvulitis began in the hospital. He had treated 30 cases and 27 went out without a trace of heart affection. A great many of these he had watched and continued to watch. The longest period for which he had watched a cured case was 15 years, and the heart was as sound 15 months ago as could be. He could not expect them to accept all his views, but they were recognised by his own students and a few practitioners who had also had the same results. He did not want to hold it up as the best and only method, but they should try to find out some method of diminishing the frequency of cardiac complication because it was such a serious and terrible thing to have for a whole life a crippled heart, and unfortunately it was very common. There was hardly a week that he did not have to admit some poor soul with a history of rheumatic fever three years ago and inability to breathe properly since. They should do everything they could by experiment or otherwise to find some method to diminish this great scourge which furnished one of the greatest opprobriums to the medicine of the present day.

Dr. BURNEY YEO said that all he had to offer were a few deductions from his own observations and experience. He was entirely in agreement with those speakers who regarded acute rheumatism as an infective fever probably of bacterial origin, and he did not quite share Dr. Pye-Smith's objection to a working hypothesis or to what Professor Tyndall called the scientific uses of the imagination. Great truths in science were often reached by hypothetical speculation. Reasoning from analogy they might be justified in thinking that acute rheumatism was due to bacterial influence. He was also entirely in accord with those who had advocated the treatment of acute rheumatism by the use of the salicyl compounds. *No one, he thought, could watch acute rheumatism* in hospitals without being convinced that there was a profound change for the better through the use of the salicyl compounds He was able to remember to have carried out a consistent treatment of rheumatism before the introduction of the salicyl compounds, and he did not share either Dr. Sansom's or Dr. Pye-Smith's view that that treatment was altogether useless and inefficient. That treatment as he carried it out was something of this kind: painful joints were enveloped in a weak alkaline and opiate lotion. If one saw the case at the very beginning one gave some full doses of opium over night for a few nights, 15 grains of Dover's powder till the joint pains had been relieved, followed next morning by a small saline draught to help elimination of the opium. During the day bicarbonate was given every four hours. If the temperature reached more than 102° or 103° F. two grains of quinine were added to each dose of the bicarbonate of potassium. If the joint pains and swellings lingered it was very common to apply a blister about two inches above the joint, and he quite failed to share either Dr Sansom's or Dr. Pye-Smith's objection in regard to the discomfort. He quite agreed with what Dr. Caton had said as to the slight inconvenience experienced by patients, supposing the blistering to have been skilfully and carefully done. He knew it was stated in books, and he had heard it said, that blistering would often produce irritation of the kidneys, but after years of experience he had never seen a single instance. He could quite believe that in the days gone by, when blistering was done on a large scale and with not much attention to the dressing, discomfort and irritation of the kidney arose, but he had never seen such a thing. The application of small blisters from place to place was important and the dressing was not unimportant. The patient's discomfort often arose from the looseness with which the dressing was applied. The blister should be slit, the dressing ought not to be allowed to get loose, but ought to be fixed firmly by sticking-plaster, and if that was done the patient would not suffer any discomfort from blistering. Although one was accustomed to notice and to be struck with the beneficial influence of the treatment by salicyl compounds in acute rheumatism he could not say that he was fond of salicylates, for he had seen so much of that cardiac depression to which Dr. Pye-Smith had called attention that he was always glad to reduce the dose and he was still more pleased when he could do without the salicylates altogether. He was surprised to hear that

Dr. Lees said that he thought the depression was due rather to the disease than to the remedy. He was amazed to think that anyone could doubt that these salicyl compounds were not depressing to the heart. He had pointed out often at the bedside that a patient after taking salicylate of soda for 24 hours would have the pulse depressed to 60 while the temperature would only be reduced to 101°. There were numerous cases of chronic disease in which patients were put under the influence of salicylate and suffered considerable depression. It was common to give this drug in cases of long duration and he had seen a woman who had been thus treated for three months at Wiesbaden for gouty affection of the eyelids with neuralgia. She had salicylate of sodium which had relieved her pain but had produced a most remarkable condition of depression. On the administration of other drugs for the relief of the neuralgia her depression cleared off and she said that she felt a different woman, no longer suffering from a depression which made her life a burden. In the influenza of the rheumatic type salicyl preparations relieved the pain, but the cardiac depression was a very serious matter. He was accustomed to give salicylate of soda or, perhaps better, salicin, which Dr. Maclagan preferred, for a few days; and when the patient was in a happier condition he was glad to leave off the salicin and take to quinine or some other drug which gave him no anxiety as to cardiac depression. At their last meeting Dr. Donald Hood, who rather advocated other treatment than by salicylates, called to his aid the testimony of Dr. Osler. Dr. Hood mentioned to them Dr. Osler's premisses, but he did not tell them Dr. Osler's conclusions. He would read them Dr. Osler's premisses and then his conclusions:—

> Medicines have little or no control over the duration or course of the disease which, like other self-limited affections, practically takes its own time to disappear. Salicyl compounds, which we regarded so long as specific in the disease, *are now known to act chiefly by relieving pain.* R. P. Howard's elaborate analysis shows that they do not influence the duration of the disease *Nor do they prevent the occurrence of cardiac complications,* while under their use relapses are considerably more frequent than in any other method of treatment.

Dr. Osler's conclusions were :—

> In acute cases with severe pain the salicyl compounds give prompt relief and *rarely disappoint us in their action. Sodium salicylate in* 15 grain doses for eight or ten days may be given. The bicarbonate of potassium in 20 grain doses may be used with it I have for the past five or six years used the oil of wintergreen recommended by Kinnicutt and have found it quite as efficacious. *20 minims may be given every* two hours in milk.

Dr. Osler further says: "Opinion is almost unanimous that under the alkaline treatment cardiac complications are less common. The combination of the salicylates with the alkali is probably the most satisfactory." Those, then, were Dr. Osler's conclusions and if they were compared with the premisses one was almost tempted to say that the voice was Jacob's voice but the hands were the hands of Esau. For his own part, he agreed with Dr. Osler that a combination of the salicyl treatment with the alkali treatment was probably the best. There was a certain amount of opinion in favour of the alkaline treatment diminishing the risk of cardiac complications and it was difficult to discover whether this was the case or not, but so long as there was a large body of opinion in favour of that view, and while they knew that the administration of alkalies altered the morbid condition of the urine, he thought it rational to combine a mild alkaline treatment with the salicyl treatment. There was another point, and that was to give patients the subjects of acute rheumatism large quantities of water to drink. In no disease was there such a loss of water as in rheumatism. It was important to supply that loss, as also in all fevers, especially as they were treated in hospitals, for he had been surprised to find how little attention to the supply of water there was in those institutions; he had often given a glass of cold water to fever patients. Knowing that in cases of rheumatic fever they had profuse sweating and high-coloured scanty urine it was an important thing to dilute the concentrated blood which had become so from great loss of water. With regard to the incidence of endocarditis in acute rheumatism the remarkable fact that the right side of the heart was almost immune from these attacks of endocarditis ought to be dwelt upon. The usual explanation that was put forward, that the left side was functionally more active than the right, was wholly inadequate. It was more probable that the endocardium on the right side of the heart was protected in some way by the condition of the blood; whether the carbonic acid in the blood interfered with the action of the toxin or whether it rendered the endocardium less susceptible he did not know. Perhaps Dr. Ewart in some of his therapeutic observations might try whether the inhalation of carbonic acid would diminish the tendency to endocarditis.

Dr. ISAMBARD OWEN said that his own observations of acute rheumatism and of its treatment had always led him to believe in the truth of the hypothesis that Dr. Maclagan had put forward for a score of years, that rheumatic fever was a specific disease produced by a specific germ and that the action of the salicyl compounds was specific. The materies morbi was actually destroyed by this substance. It had been objected to this view of the action of the salicyl compounds that they did not succeed in stopping the disease in all cases. That he confessed. His own impression was that salicyl compounds would stop rheumatic fever in every case if the patient could stand sufficient of the drug to saturate the fluids of the body up to the necessary point, and that point might differ according to the case and according to the patient, and the patient's susceptibility in regard to the nervous system with regard to salicyl differed remarkably. A certain proportion of cases arose in which the toxic effects on the nervous system were reached before the necessary saturation of the fluids was obtained, and one had to stop short before one had succeeded in efficiently treating the rheumatic fever. He was surprised to read in Dr. Osler's work his statement with regard to the effect of remedies in acute rheumatism, but as Dr. Osler put the dose of salicylate of sodium at 15 grains and did not specify the periods at which the doses were to be repeated—he supposed he meant every six hours—his surprise vanished. For in most cases of rheumatic fever it was certainly necessary to give the drug in larger doses or at more frequent intervals. He himself had never found reason to apprehend the depressing effects of the drug. He did not propose to enter into detail into the action of the drug with respect to the rate of the pulse or into any details of its action, but he would merely, taking the broad ground, state that personally he had administered salicylate of sodium in many hundreds of cases, and very freely indeed, and very seldom had he had to suspend the administration of the drug owing to any depressant effects upon the patient, and where depressing effects had resulted they had presented themselves to him as effects rather upon the central nervous system than upon the heart, and, speaking broadly, he had very seldom seen any reason to fear salicylate of sodium in the necessary doses. It had further been objected to these views of the action of the salicyl compounds that they did not prevent or tend to the cure of what used to be called complications, the effects upon the endo- and peri-cardium. He would say personally that they had prevented a great deal of pericarditis by cutting the attacks of rheumatic fever short before pericarditis had developed. He did not think their use materially prevented the development of endocarditis; his experience tended to show that the effects of the disease upon the endocardium were among the earliest effects produced in all given cases; he was almost disposed to believe that the endocardium was one of the earliest parts affected in rheumatic fever. It was true that the murmur characteristic of it might not be heard at the outset, but then the affection of the heart valves required a little time to develop to that point at which it was capable of producing a change in the heart sounds, and rheumatic endocarditis produced at the outset no symptoms by which its presence might be recognised. In his own hospital experience the proportion observed of murmurs which developed after the patient's admission was exceedingly small; he thought about one in 30. That was the result of the statistics which he had gathered at St. George's Hospital many years ago. It was objected that over endocarditis and pericarditis the salicylate compounds exercised no curative effect. The answer was given practically by Dr. Garrod that day last week when he pointed out that it was quite the habit of diseases produced by specific germs that the germs should give rise to several toxins which enter into the circulation, and that although a remedy might destroy the parent germ and might destroy or counteract the effect of some of the toxins other toxins might remain over which the remedy had no power. That was seen in the treatment of diphtheria by anti-diphtheritic toxin. This was corroborated by rheumatic fever in a consideration which was often overlooked, and that was that endo- and peri-cardial lesions differed from the articular lesions not only in situation but in kind.

That difference was masked under the common name of inflammation which was generally applied, but to his mind the name inflammation was quite inaccurately applied to the articular lesions of acute rheumatism. Redness, heat, and swelling were considered inflammation, but they understood it as a process in which the leucocytes—he believed the all-essential part—proliferated in the inter-vascular spaces and finally caused thickening or destruction of the tissues. But there was nothing of that kind in rheumatic fever; the exudation which caused the swelling of the joint was mainly synovial, and if not altogether synovial was more or less serous in addition. The fluid effused about and inside the joint in rheumatic fever contained scarcely any fibrinous exudation, and the exudation of the leucocytes was no more than would be expected in an effusion produced by any other kind of hyperæmia. Although the affection might have lasted in a joint in an acute form for a week, for a fortnight, or for three weeks, yet when the pain had gone the patient moved his joints freely, or when it was cut short altogether by the action of salicyl compounds, in 48 hours from the disappearance of pain in the joint the patient could move his joint freely and recovered without permanent trouble in the joint. It was a hyperæmia but not a true inflammation, as was pointed out by Todd somewhere about 50 years ago. There were exceptional cases in which the hyperæmia set up a process of inflammation, a small proportion of cases in which a certain amount of inflammation was set up in the joint and the joint was found becoming œdematous externally. In these cases some time elapsed before the joint could be moved freely. There was a still rarer class of case in which tuberculous inflammation had existed in the joint before and which ultimately merged into a tuberculous joint. But in the majority of cases in acute rheumatism the joint recovered without thickening or destruction of the tissue. The scope of the discussion as laid down included the prophylaxis of acute rheumatism and into that subject he endeavoured to make some investigation some years ago by making inquiries into the status and habits of a large number of patients. This was at the time when he was medical registrar at St. George's Hospital. In spite of his labour he was sorry to say he gained very little information. Rheumatic fever patients he found on the whole were less alcoholic than on the average, but that was probably accounted for by the comparatively youthful age of the patients. The common belief that beer was obnoxious to rheumatism obtained a certain amount of support; the proportion of beer- to spirit-drinkers was considerably in excess of the ordinary ratio. There was a belief at that time that suppression of perspiration had much to do with the genesis of acute rheumatism and that led him into inquiring as to the habitual perspiration of these patients, whether it was in excess or in defect, or about the same. He did, however, find that in the proportion of 58 to 43 per cent. patients with rheumatic fever appeared to show one or other peculiarity; further than that his inquiries led to no result. The question of climate and situation was no doubt one of some importance and there was a general belief that rheumatic fever was a malady especially attached to low-lying damp districts. That did not seem to be borne out by statistical evidence. Some 15 years ago he made a preliminary inquiry on the part of the International Investigation Committee into the general prevalence of rheumatic fever in this country. It appeared that there was no part of this country which could be said to be free from rheumatic fever—he meant the whole of the United Kingdom—and there were very few places in which it was not said to be a common malady. The British Medical Association Investigation Committee had made inquiries and one point was the character of the locality in which the patient was living at the time he was attacked, and the results were quite contradictory to the ordinarily received opinions on the subject, for the great majority of patients affected were said to have been attacked while living either in high, or dry, or exposed, or high and dry, or high, dry, and exposed, localities. The largest group was the group from the high, dry, and exposed localities. That agreed with a certain amount of personal experience that they had had at St. George's Hospital. They had a large convalescent hospital at Wimbledon which was on the top or a little down the slope of a hill on a gravel soil, protected from the north and east, and facing south and south-west, but the liability to rheumatic fever in this hospital was so great that for many years they had never sent a convalescent rheumatic patient there. Out of the rheumatic fever patients sent when he was there he did not think 10 per cent. escaped from a return of the malady. This bore out the results of the Collective Investigation Committee. He would not follow the previous speakers into the treatment of the onset of cardiac complications, but he would point out one thing in regard to the commencement of pericarditis. He was surprised to hear in the various treatments employed at the onset no mention of the very old-fashioned remedy which he was accustomed to employ and with considerable benefit: he meant the application of eight or a dozen leeches to the region of the heart, and this old-fashioned remedy, now almost dropped into disuse, had appeared to him in some cases if not absolutely to check the pericarditis at any rate to relieve the patient of the most serious symptoms and considerably to modify the intensity of the process.

The CHAIRMAN asked Dr. Caton what particular nerves they were to which he applied the blisters. With regard to Dr. Pye-Smith's views as to the bacterial origin of rheumatism, unless some working hypothesis was brought forward they would never arrive at any result. He ventured to say that the Listerian treatment would not have been discovered had not Lord Lister formulated in his own mind the possibility of the treatment which he afterwards carried out so successfully.

Dr. C. C. GIBBES said that there were certain cases of rheumatism in which the salicylate treatment failed on account of the toxic effects produced before the patient was saturated with one of the salicyl compounds. He thought sufficient importance had not been given to the nature of the salicylate compound prescribed. Looking at the British Pharmacopœia as it at present stood if they prescribed salicylate of soda the chemist simply mixed up the cheapest drug on the market. There were four different kinds of salicylate—the natural, the artificial, the pure, and the purest form. The artificial or the British Pharmacopœia form was infinitely the cheapest of the whole lot, and he believed it was used in a large number of hospitals. He had given the salicylates in various forms and at various periods, and he thought it was of the greatest importance that the quality of the drug should be determined and also the way in which it was given. Taking the quality of the drug, Mr. Williams had investigated this matter about the time Professor Latham wrote about the natural salicylate of soda, and he found that the impurities which, according to Dr. Charteris, produced most of the toxic effects were chiefly the ortho- and meta-cresotic acids. Later experiments by Duncan and Flockhart proved that the impurities in the present artificial salicylate were para-cresotic acids. Clinically most were agreed that the toxic effects produced by the salicylates 20 years ago and now were different. About the way in which it was given, he had tried it in 20 grains every three hours and more quickly, and he found there was no comparison in the methods. If one wanted the full and the best effects of any salicylate compound he must give it with big doses to start with and repeat them for two or three days, according to the patient's idiosyncrasy. Personally he found that taking it himself there was no comparison between the artificial drug of the British Pharmacopœia and the natural drug. The toxic effects, he believed, were due to the para-cresotic acid. In the British Pharmacopœia form they could not get the patient in a large number of cases sufficiently under the influence of the salicylate because of the para-cresotic acid. In the natural form the patients could take larger doses; the shortness of breathing and delirium did not occur. That was his experience in rheumatism and he had taken the salicylate of soda himself. Why the Pharmacopœia Committee of the General Medical Council should have adopted and made official the cheapest form of the drug in the market and the most impure was really a puzzle, and it would be greatly to the benefit of rheumatic patients if it was laid down that the salicylate given must be either the purest form or else the natural one. Otherwise he did not believe that the salicylate in any form, such as the artificial, could be sufficiently pushed for the full benefit to be given to the patient. As to the time when it should be given if they gave it early they got infinitely better effects. Experience in the hospital and in private was different. In private practice they had a chance of giving the drug quickly and in the hospital they did not get the patient until the disease had got a certain hold. If statistics were to be drawn between alkali and salicylate treatment they must know the drug given and they must know the time when the treatment was started.

Dr. CATON said he was asked where he applied the blisters to the first, second, third, and fourth dorsal nerves which Gaskell and Sherrington thought were closely associated with the heart. He applied the blisters to the region between the clavicle and the nipple; they would be effective behind but they would interfere with the patient's rest. Either to the right or to the left the blisters were applied, for the heart was as much associated with those nerves to the right as to the left.

Dr. WILLIAM KEEN asked if the urine were kept alkaline whether there was less chance of heart complications.

The discussion was closed by Sir RICHARD DOUGLAS POWELL, whose remarks are printed in full on page 920 of this issue of THE LANCET.

Dr. EWART said that the debate had not brought forward any real suggestion as to prophylaxis. They found a great diversity of opinion not only as to the nature of rheumatism but as to the mode of the action of the salicylates and as to their scope of action. They had still before them the whole inquiry as to the treatment of rheumatism and underlying that inquiry was the nature of rheumatism and its mode of manifestation. It had been said that rheumatism was an affection of the heart. How was it that 50 per cent. of the cases were to be found going about several years afterwards with perfectly normal hearts? It required the most perfect mechanism in its study and for that reason it seemed to him that that was an occasion on which they might bring the matter before the profession so as to promote a combined action for the purpose of the study of rheumatism, and these views had found expression in the motion which he had placed before them:—

> That in the opinion of this society much useful knowledge might be obtained for the prevention of heart disease and other affections of rheumatic origin were fuller data as to the prevalence and distribution of acute rheumatism available for study.

Dr. Ewart suggested that this motion should be sent to the Local Government Board, but after some further discussion, in which Dr. GIBBES, Dr. VINRACE, and Dr. MACLAGAN joined, this was withdrawn.

Dr. A. B BLACKER seconded Dr. Ewart's motion, which was carried.

EDINBURGH OBSTETRICAL SOCIETY.

The Chronology of Ante-natal Life.—Double Ovariotomy.—Chylous Ascites —The Treatment of Eclampsia by Saline Infusion —Pathological Amenorrhœa from other than Constitutional Causes —Microscopical Demonstration of the Embryo of the Deer.

A MEETING of this society was held on March 14th, Dr. MILNE MURRAY, the President, being in the chair.

Dr. J W BALLANTYNE read a short communication on the Chronology of Ante-natal Life. He demonstrated a schedule of the divisions of ante-natal life which he had constructed on the "space-for-time" method which Mr. Jonathan Hutchinson had introduced into medical case-taking. In the scheme each space represented a week and the whole of the intra-uterine period of ante-natal life was extended, therefore, to 40 spaces. The leading subdivisions were marked off by thick and thin lines; in this way germinal life was divided off from embryonic, and embryonic from fœtal, and fœtal from neo-natal. At one side were numbers indicating the age of the pregnancy in weeks and at the other side were some of the great events, such as impregnation, organogenesis, growth, birth, adaptation, &c By means of the schedule he claimed that a more clear conception could be formed of the phenomena of ante-natal life and of their relation to each other and to the progress of gestation. It might also be used as a case-taking scheme in obstetric practice in which any unusual occurrences in pregnancy might be noted down in their appropriate place and their possible bearing on the condition of the fœtus, as discovered at birth, made evident. Dr. Ballantyne also demonstrated a second scheme in which an attempt had been made to represent the projection of the various periods of ante natal life into one another, for it could not, of course, be affirmed that the whole of the organogenesis of the body was completed in the embryonic period of ante-natal life, some of it was postponed till the fœtal period. This projection or overlapping was brought out graphically in the second schedule.

Dr. HALLIDAY CROOM read a note on an interesting case of Double Ovariotomy. The patient, aged 18 years, was first admitted to Dr. Croom's ward in the Royal Infirmary in July, 1897. She complained of a swelling of the abdomen which had been observed for 16 months. Before admission the tumour had been tapped three times. On examination extensive hydrothorax was discovered and the abdomen was enormously distended with fluid. The right pleural cavity was tapped and 144 ounces of serous fluid were removed and a few days later 280 ounces of similar fluid were removed from the abdomen. A large tumour was then detected in the abdominal cavity; it was irregular in shape, very hard, and it presented all the features of a malignant ovarian tumour; it was considered hopeless to attempt any radical operation. From July, 1897, to April, 1898, the patient remained in the ward and during that time the abdomen was aspirated every fortnight and the right pleural cavity was tapped on four occasions. In April, 1898, the conclusion was forced upon Dr. Croom that since the patient's general condition was no worse than on admission and the tumour had not changed in any way the condition might not after all be malignant and operation was accordingly undertaken on April 5th. Dr. Croom then removed the largest ovarian dermoid he had ever seen, but the operation was comparatively simple and the patient made an uninterrupted recovery. The right ovary was left intact as it seemed healthy. The patient went home to Shetland perfectly well on June 7th. She was readmitted to Ward 28 on Sept. 30th, 1899, when she complained of swelling of the abdomen which she had noticed for six weeks. Examination revealed a large, hard, semi-solid tumour growing upwards in the abdominal cavity, and this was diagnosed as an ovarian cystoma growing from the other ovary. Operation proved this tumour to be cystic, but owing to the numerous adhesions and to the fact that the tumour was intra-ligamentous the operation was very tedious and the patient became extremely collapsed. However, she speedily recovered and left the ward a month later perfectly well. The tumour was examined at the Laboratory of the Royal College of Physicians of Edinburgh, whence a report was sent that it was a cystic papilloma of the ovary. Dr. Croom referred to the difficulty of diagnosis of abdominal tumours and the importance of opening the abdomen in doubtful cases.

Dr. HALLIDAY CROOM also read a paper on Chylous Ascites with an illustrative case. He said that obstruction of the thoracic duct, especially if gradual, might give rise to no symptoms whatever, since anastomotic channels were established through which the lymph and chyle entered the circulation. However, in other cases congestion of the lymphatic system did give rise to definite signs and this was especially so when the lacteals of the abdominal cavity were within the area affected. A few cases had been recorded in which chylous fluid was found secondarily in the pleural cavity and only 63 cases of chylous ascites had been recorded. The notes of Dr. Croom's case showed that the patient, a female, aged 39 years, was admitted to Ward 28 in the Royal Infirmary on Sept. 29th, 1899, complaining of swelling of the abdomen and gradually advancing weakness and emaciation These symptoms she had observed for three months, previously to which time she had been perfectly well. Examination of the abdomen revealed the presence of free fluid and an irregularly shaped and evidently malignant tumour The abdominal cavity was aspirated and 380 ounces of fluid were removed. The fluid at first sight presented all the appearance of pus but on examination it was found that it was more mobile and had a sweetish milky odour and that after standing for 24 hours a slight creamy layer formed on the surface. Dr. T. H. Milroy reported that the fluid consisted partly of finely emulsified fat but more largely of a granular débris consisting mainly of fat The patient did not improve but became more and more emaciated and a fortnight later 350 ounces of similar fluid were removed. She died five days later. A post-mortem examination was made by Dr. D. A. Welsh. A cancerous tumour was found at the pyloric end of the stomach and the mesentery and the glands were secondarily infiltrated. The small intestine showed an immense number of small cancer nodules surrounding the lacteals close to the mesenteric attachment The thoracic duct and receptaculum chyli were carefully dissected out and were found healthy, but there was a mass of glands pressing on the receptaculum. Dr Croom then referred to the literature on the subject and pointed out the differences which some authorities held to exist between chylous ascites and adipose ascites.

Dr. R JARDINE (Glasgow) made a further contribution on the Treatment of Eclampsia by Saline Infusion. In the last session he had submitted to the society the results in 12 cases treated in this way; he had published five more and he now gave details of another series of five cases In every case the diuretic effect of the saline injection had been prompt and marked The solution used consisted of one drachm each of chloride and acetate of sodium to the pint of sterilised water From two to three pints were injected underneath the breasts between them and the chest wall or, if required, into the loose abdominal subcutaneous tissue These injections could be repeated This treatment was accompanied by a saline purge, sometimes with bromide and chloral and 10 minims by hypodermic injection of tincture of veratrum viride Of the 22 cases six of the patients had died, one died from perforating duodenal ulcer One of the patients was treated with ordinary saline solution This result compared favourably with other lines of treatment in eclampsia, especially after taking into consideration that many of the patients had been seized with fits for several hours before admission to the Glasgow Maternity Hospital Some had been prognosed as hopeless There was no risk in giving these large infusions, out of at least 200 injections he had never found any abscess formation Of course, strict aseptic precautions had to be followed In one fatal case conjugate deviation of the eyes to the left was present, with the face slightly drawn to the right, and the left arm seemed paralysed, but post mortem no brain lesion was found though its substance was somewhat anæmic —THE PRESIDENT Dr S McVil Dr HALLIDAY CROOM, Dr JAS RITCHIE Dr J LOUIS Dr F W N HAULTAIN and Dr J W BALLANTYNE discussed the paper

Dr F W N HAULTAIN read a paper on Pathological Amenorrhœa from other than Constitutional Causes Details of cases of atresia hymenalis, atresia vaginalis atresia cervicis and the necessary operative treatment were given There were also cases of amenorrhœa due to functional inactivity of the uterus or the ovaries or to their insufficient development In other cases the uterus and ovaries were apparently normal, and yet menstruation did not appear These were evidently due to some affection of the central nervous system Acquired amenorrhœa might be due to shock fear of pregnancy or other nervous cause Prolonged rest from work was very helpful in the treatment of this class The intra uterine application of electricity, negative pole (Apostoli) was very helpful in some cases of cessation of the flow after it had been in regular function In acquired amenorrhœa due primarily to want of ovarian activity alone ovarian extract was beneficial, the dose usually given was 15 grains daily but 40 grains daily might be given without any untoward effect

Dr J FOULIS gave a microscopical demonstration of the Embryo of the Deer showing that the umbilical cord had no amniotic covering

ROYAL ACADEMY OF MEDICINE IN IRELAND

SECTION OF PATHOLOGY

Growth of the Typhoid Bacillus —Histology of Tuberculosis of the Intestines and the Liver —Corneal Dermoid Tumour —X Rays in Dental Pathology —Exhibition of Specimens

A MEETING of this section was held on Feb 23rd Dr A C O'SULLIVAN the President being in the chair

Professor E J MCWEENEY read a note on the Effect of Certain Varieties of the Nutrient Medium on the Growth of the Typhoid Bacillus in which he stated that experimental cultures made by him showed that (1) the growth improved with increasing addition of decinormal sodium hydrate to the unneutralised gelatin up to the beginning of alkalinity (indicator phenolphthalein) (2) the addition of salt in quantities varying from 0 1 to 1 per cent, to the fully neutralised gelatin (same indicator) made no difference in the amount of growth, (3) the omission of both salt and peptone exercised no appreciably unfavourable influence on the growth in gelatin made with meat decoction, (4) addition of quantities of phenol to gelatin in the proportion of 0 05 to 0 5 per cent exercised an inhibitory influence on all growths when the addition exceeded 0 07 per cent, between 0 05 and 0 07 the effect was to check the anaerobic growth, and (5) Parietti's solution added to ordinary bouillon suppressed the growth of the typhoid bacillus when the bacillus coli was also present The addition of nine drops (0 3 cubic centimetre) to 10 cubic centimetres of bouillon to which was subsequently added a few drops of a mixture containing both the typhoid bacillus and the bacillus coli (e g, bile from a patient dead from typhoid fever) caused such retardation of the growths produced by plating out the tube on gelatin as to make them closely resemble true typhoid bacillus colonies Tests however, proved that nothing but bacillus coli grew in the Parietti's tube, although ordinary agar plates from the same material yielded an abundance of typhoid bacillus colonies It was on the suppression of the typhoid bacillus by the Parietti test that the speaker desired to lay special stress —The PRESIDENT said that in the first experiment on the typhoid bacillus it was really decrease of acidity that was being estimated It would be interesting to know if a further condition of alkalinity would make the growth go off or possibly make a stronger growth The observation that phenol acted first on the anaerobic growths *might be explained by the fact that typhoid bacilli were what* were called facultative anaerobes—that is, their natural mode of growth was aerobic and their anaerobic growth was, therefore strained and the inhibitory drug acted first on the restrained kind of growth The method of Parietti was very useful for the analysis of water, but it was entirely useless for analysing milk for the typhoid bacillus, because there were so many organisms in milk which resisted a mixture of hydrochloric acid and carbolic acid better than the typhoid bacillus —Professor MCWEENEY in reply, said he agreed with the statement that Parietti's solution was of no use for the analysis of milk He acknowledged the justice of the correction with regard to the reaction—he should have said decrease of acidity

Professor MCWEENEY showed preparations illustrating the Histology of Tuberculosis of the Intestines and Liver They were taken from a patient who had died from diarrhœa due to tuberculous enteritis The floor of the very extensive ulcers was composed of granulation tissue consisting of cells with simple and polymorphous nuclei but seemingly devoid of giant cells Enormous multitudes of tubercle bacilli were lying between these cells and were often actually in contact with, but not within them, yet the tissue showed practically no sign of caseation—a remarkable fact in view of the extensive areas of caseation met with so commonly in tuberculous lymphatic glands where even the most careful examination failed to reveal a single bacillus The toxin that produced caseation might conceivably be contained within the bacillary bodies and only become free by their break down This at any rate would be an explanation of the frequent want of association between demonstrable bacilli and extensive caseation The liver sections constituted a classic object for the study of the histogenesis of tubercle showing as they did tubercles in the very earliest stage of development when they consisted of only a few epithelioid and lymphoid nuclei Professor McWeeney had arrived at the conclusion that many of the tubercles began by proliferation of the nuclei of intra lobular capillary endothelium

Mr ARTHUR H BENSON and Dr H C EARL described and showed sections of a Dermoid Tumour removed from the eye of a child aged four years The growth straddled the cornea scleral junction but extended more on the cornea than on the sclerotic and occupied the whole thickness of the cornea It was only slightly raised above the surrounding tissues and was of a creamy white colour and slightly rough or rather unpolished, on the surface It grew contrary to the usual custom, at the inferior nasal side and extended almost to the corneal apex

Mr GEORGE J GOLDIE demonstrated the usefulness of the x rays in dental cases where other methods of diagnosis had failed The conditions in which he found the new agent most valuable were (1) Fracture and dislocation of teeth in the jaw, (2) fracture of the jaw itself, (3) the diagnosis of inflammation round the roots of teeth (alveolar abscess), (4) the diagnosis of inflammation round the roots of teeth giving rise to symptoms remote from the seat of lesion (neuralgia trismus &c), (5) the treatment of impacted and in coming wisdom teeth (6) the normal eruption of the permanent teeth following the temporary or milk teeth (7) the abnormal eruption of the same, (8) the absence or presence of any missing tooth in the jaw when its eruption has been abnormally delayed, (9) the regulation of teeth malposed in the jaw, (10) many purely clinical dental conditions which could only be mentioned without being described, (11) exostosis of roots of teeth, and (12) foreign bodies in the antrum of Highmore —Dr WILLIAM S HAUGHTON then described [illegible] various difficulties encountered had been overcome "cut celluloid" photographic films, enclosed in orange and black paper bags, which were again enclosed in an india-rubber bag specially manufactured, as most samples of rubber contained so much sulphur as to render them very opaque to x rays. These films had to be cut small enough to go inside the patient's mouth, and the best position in which to place the film for each individual tooth required a careful study of the anatomical relations of each tooth to its surrounding alveolus. For a clamp to hold the film in position he preferred the finger of a skilled assistant in the mouth, while the other hand made counter-pressure on the head outside. This, combined with the head-rest of a dental chair, had proved very satisfactory. The best working distance of the tube from the film was from eight to 10 inches and the usual exposure was from 90 seconds to two minutes.

Professor McWeeney exhibited a specimen of Spontaneous Rupture of the Œsophagus. The patient, an alcoholic male, aged 40 years, had retched violently before going to his work. His face and neck became swollen and his breathing difficult, so that he was forced to go to the Mater Misericordiæ Hospital, where he died a few hours after admission. At the necropsy enormous swelling of the face and neck, due to subcutaneous emphysema, was found. The primary lesion was in the posterior mediastinum, the contents of which were coated with grey pultaceous matter, which could be seen escaping through a longitudinal rent half an inch long in the anterior surface of the œsophagus just above the diaphragm. The immediate cause of death was intense œdema of both lungs, associated with failure of a fatty right heart.

Dr. H. O. Earl exhibited a specimen of Cyclopian Fœtus, with Supernumerary Fingers and Diaphragmatic Hernia.

Liverpool Medical Institution.—A meeting of this society was held on March 22nd, Mr. Edgar Browne, the President, being in the chair.—Dr. K. Grossmann showed a case of Double Congenital Anophthalmos in a child 11 weeks old. The eyelids turned inwards and opened through a small rima into a conical space lined with conjunctiva. The eyelashes were well formed, with an absence of puncta lacrymalia. The conjunctiva at the fornix formed a straight cone whose apex in the left eye was a whitish, and in the right eye a bluish, point. The well-developed state of the adjacent structures indicated that the arrest of development of the eyeballs and their probable subsequent disappearance had taken place at an advanced stage of fœtal life.—Mr. W. B. Bennett showed a woman suffering from Motor Aphasia, Right Hemianæsthesia, and Paralysis of the Right Side of the Tongue, but no hemiplegia; he considered the lesion to be a softening in the sub-cortical area of the brain.—Mr. G. Reinhardt Anderson read notes of a case of Strangulated Obturator Hernia in a woman, aged 75 years. The patient was seized with pain in the left thigh and vomiting; when first seen, 24 hours later, the vomiting had ceased and the pain was not so marked; next day all the symptoms pointed to complete obstruction, there being fæcal vomiting and abdominal distension. There was some fulness in the left femoral region and the diagnosis was that of partial enterocele in the left femoral canal. Operation by incision over the femoral region revealed nothing, the lump felt being an enlarged gland. The patient was unrelieved and too ill apparently for laparotomy. Five hours later the femoral wound was reopened and a deep dissection revealed a hernia through the obturator foramen. This was reduced and the patient made a rapid recovery and was now well.—Mr. Rushton Parker congratulated Mr. Anderson on the promptitude with which he had acted and thus saved the patient's life; the condition was one of great rarity and in an operative experience of 510 herniotomies he had never met with obturator hernia.—Dr. Lloyd Roberts described the sequence of the symptoms and physical signs in the course of a typical case of Mediastino-pericarditis and read notes of a case he had met with in a boy aged five years.—Dr. William Alexander read a paper on the Prevalence of Ophthalmia in Liverpool: its Prevention and Treatment. In three years nearly 1000 cases of ophthalmia in various forms had been admitted into the Liverpool Workhouse Infirmary. These all came from the lowest parts of the city and many of the children were admitted direct from their attendance at school. In one-tenth of the cases there was impairment of vision; some were temporarily blind, and in many the eyes were hopelessly lost. To prevent the disease it would be necessary to have ophthalmia notified as a contagious disease and arrangements made for the effectual treatment of each case notified before its return to school. The patients' homes should be visited and all the family inspected, for often other children had acquired the disease in a latent form. All schools should be periodically visited and latent cases eliminated. The treatment of granular lids was described as hygienic and local and the methods for the former adopted by the Select Vestry were discussed. He thought that the best results in the treatment of trachoma were obtained from the use of the solid sulphate of copper in cases where the discharge was slight and the granules distinct; when the discharge was greater he used nitrate of silver solution. The relations between follicular conjunctivitis and granular lids were discussed and it was shown how difficult it was to diagnose one from the other. Follicular conjunctivitis was comparatively rare in Liverpool and many surgeons were doubtful of its existence as a distinct disease. The paper was illustrated by cases, photographs, drawings, and lantern slides.—Dr. K. Grossmann urged the importance of classification and considered the follicular and granular forms as distinct diseases and not as stages in the same disease. Granular conjunctivitis he considered a rare disease in Liverpool after a long hospital experience in one of the poorest parts of the city. The clinical facts were the guides as to prophylaxis and treatment.—Dr. A. S. Griffith stated that in every case of muco-purulent catarrh he had found the Koch-Week's bacillus; in the scanty discharge of chronic granular conjunctivitis there was no organism found to which the condition could be ascribed, but when trachoma developed the Koch-Week's bacillus was found in large numbers. He assumed that bacilli entered the tissues and, acting as an irritant, resulted in the formation of granules, and that the particular bacillus was probably Koch-Week's bacillus acting with a small amount of virulence.—Mr. Richard Williams, Mr. T. H. Bickerton, Dr. S. H. House, Dr. C. J. Macalister, Professor R. W. Boyce, and Mr. C. G. Lee also took part in the discussion, and Dr. Alexander replied.

Sheffield Medico-Chirurgical Society.—A meeting of this society was held on March 15th, the President, Dr. D. Burgess, being in the chair.—Dr. A. J. Hall showed cases of (1) Congenital Syphilis, (2) Lichen Syphiliticus, (3) Tuberculous Syphilide simulating Lupus, and read notes of a case of Iodide of Potassium Eruption.—Mr. W. Dale James showed: 1. A case of Pityriasis Rubra Pilaris in a man, aged 30 years. It began when he was eight years old upon his right shin, which was the only patch he had. The case had been reported frequently, the patient having four years ago been under Dr. J. F. Payne at St. Thomas's Hospital. The mortar-like accumulation and the presence of plugs in the follicular openings were very diagnostic. 2. A beautifully developed Tertiary Macular Syphilide.—Mr. Simeon Snell showed the following patients: (1) A youth, aged about 20 years, with a large solitary Tubercle of the Iris (left eye). The lungs were free from disease, but there was thickening of the left epididymis; (2) a boy with Ectropion treated with Thiersch Graft; (3) two cases of Symblepharon treated with Thiersch Graft; (4) a man with a Piece of Steel embedded in the Retina; (5) a child with Palsy of both External Recti after Diphtheria; and (6) a woman with very marked Periarteritis of the Central Retinal Artery.—Mr. Snell also exhibited: (a) A water-colour drawing of a Congenital Papilloma of the Conjunctiva which was sufficiently long to protrude through the palpebral fissure and to rest on the lower eyelid; (b) a series of microscopic photographs, including amongst them three instances of Rodent Ulcer, microscopical sections of which were also shown; (c) Embolism of a Branch of the Central Artery of the Retina (perimeter charts of four cases).—Mr. Snell also showed a beautiful work which was illustrated by photographs from large water-colour drawings of forest and other rural scenery executed by a patient who had several years since undergone cataract extraction at his hands. The same gentleman had since the operation been a successful exhibitor at the Royal Academy.—Mr. R. J. Pye-Smith showed two cases in which he had performed Laparo-pylephleb-anastomosis (the operation introduced by Dr. D. Drummond and Mr. Rutherford Morison in 1896). 1. A girl, aged 18 years, had been under the care of Dr. Burgess at the Sheffield Royal Hospital with enlarged liver and spleen and ascites for three years. She had been tapped frequently, and as the abdomen refilled in a month.

Dr. Burgess requested Mr. Pye-Smith to operate. At the operation (on Nov. 10th, 1899) the capsule of the liver was found to be thick and the spleen to be greatly enlarged. The liver, spleen, and omentum were attached to the anterior abdominal parietes. During the four months that had elapsed since the operation a considerable quantity of fluid had gradually accumulated, but the improvement in this and in other respects had been very great. 2. A man, aged 31 years, was admitted to the Sheffield Royal Hospital, under the care of Dr. Burgess, in September, 1899, for hæmatemesis. Whilst in the hospital slight ascites developed, but subsided under medicinal treatment. There was an alcoholic history and Dr. Burgess diagnosed cirrhosis and asked Mr. Pye-Smith to operate. At the operation (on Jan. 16th, 1900) a hob-nailed condition of liver was found with an enlarged spleen, but no ascites. The left lobe of the liver was attached to the anterior parietes and the omentum was fixed along the edge of the wound. The patient was now, two months after the operation, in a comfortable condition. It was, of course, too early to judge of ultimate results in either of these cases. —Dr. Sinclair White showed: 1. Unusual Gall-stones. 2. A boy on whom Estlander's Operation had been performed five years previously. The lung on the affected side had regained almost its normal size, and there was no lateral curvature of the spine and very little deformity. 3. A rapidly growing Sarcoma of the Scapula in a case which was subsequently dealt with by the total excision of the scapula. 4. A woman with *Early Cancer of the Left Breast, the right* mamma having been removed for cancer six months previously. There was no evidence of cancer elsewhere.—Dr. Stanley Riseley showed a man, aged 44 years, who seven years ago was struck on the Inner Side of the Cornea by a piece of coal. The patient said that three years afterwards a growth appeared in the same situation and that 18 months subsequently part of the growth was removed. He came under Dr. Riseley's care four months ago with a growth firmly attached to the cornea and conjunctiva which on microscopical examination proved to be an epithelioma. There were apparently no glands involved. The growth had rapidly increased in size. The patient would not consent to *operation.*

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Feb. 20th, the President, Mr. W. H. Horrocks, being in the chair.—Dr. A. Bronner showed specimens illustrating Growths of the Nose.—Dr. R. H. Crowley showed the following specimens:—(1) Cancer of the Uterus with Secondary Deposit in the Lungs; (2) a Thrombosis of the Pulmonary Artery firmly adherent and evidently of old standing; (3) Perforating Tuberculous Ulcer of the Small Intestine; and (4) the Brain of a Microcephalic Idiot three years old, the child weighing 14½ lb. and the brain weighing 11 oz.—Dr. C. F. M. Althorp showed a specimen of a very extensive Tumour of the Thyroid Gland occurring in a child seven years old. The patient, who had been apparently in good health till about three months before admission to hospital, was said to have developed whooping-cough and soon afterwards the mother noticed an enlargement of the neck. The child was found after admission to suffer from attacks of severe inspiratory dyspnœa, which were at first relieved by medicine (belladonna). But this drug soon lost its effect and failed to control the paroxysms. The thyroid body was seen to be greatly enlarged laterally and the isthmus was much thickened. The isthmus of the thyroid was exposed and divided between two ligatures. This gave great relief and for a fortnight the child had no attack of dyspnœa; at the end of that time, however, the patient had another paroxysm which proved fatal. On post-mortem examination there was found to be a large tumour of the thyroid body which spread downwards into the mediastinum completely surrounding the trachea and invading the wall of the right auricle. The growth was a lympho-sarcoma.—Dr. R. C. F. Rabagliati showed a Portion of the Ramus of the Lower Jaw which had been removed by operation. The patient had a cystic swelling of the jaw which had been repeatedly tapped without relief and which was supposed to be sarcomatous. The implicated portion of the jaw was consequently removed.—The President showed a Right Tubal Pregnancy of about six weeks' duration which had ruptured into the broad ligament and was removed by abdominal section.—Dr. J. Metcalfe showed two Sarcomatous Tumours which had been removed from the popliteal region at the site of an old bullet-wound received in battle 18 years before.—Dr. T. Jason Wood related a case of Ovarian Tumour of an unusual character. The *patient was a married* woman, aged 48 years, who was admitted to hospital on July 29th, 1899, with a history of abdominal pain and swelling of six months' duration. The abdomen was uniformly distended by a tense cyst which reached two inches above the umbilicus. There was much tenderness on pressure. The flanks were resonant to percussion. On vaginal examination the uterus was found to be high up and fixed. On August 4th, under the influence of ether, the abdomen was opened below the umbilicus. The peritoneum was greatly thickened and the cyst was universally adherent. It was multilocular in character and some of the loculi contained fœtid green pus. During separation *of the cyst the* wall gave way *in places* and *allowed some* of the pus to escape into the peritoneal cavity. When all the adhesions had been separated it was found to be possible to remove the cyst, there being no trace of a pedicle. The small intestines were confined to the upper part of the abdomen by adhesions so that the cavity occupied by the tumour remained. It was washed out with hot water and loosely packed with alembroth gauze; the end of the gauze was brought out of the wound, which was closed, and a cotton-wool dressing was applied. The ovaries could not be recognised owing to the great inflammatory thickening of the peritoneum. The gauze was removed after 48 hours and a tube was substituted. The patient made a *good recovery* and *was discharged on Sept. 16th.* Dr. Wood suggested that the absence of a pedicle was to be accounted for by the ovary becoming detached from its usual connexions and then undergoing cystic change.—Dr. J. Basil Hall read a paper on Gastrostomy with an account of two cases. He strongly advocated the performance of gastrostomy in cases of malignant disease of the œsophagus and urged that the operation should not be delayed after the power of swallowing solid food was gone.—The President, Dr. Althorp, Dr. Wood, and Dr. Lodge took part in the discussion.

EPIDEMIOLOGICAL SOCIETY.—A meeting of this society was held on March 16th, Dr. Franklin Parsons, the President, being in the chair.—Mr. T. Robinson, county medical officer of Leicestershire, read a paper on Measles, its Distribution and Control, being the experience of an epidemic of over 2000 cases. He said that the borough of Burton-on-Trent in 1898, when he held the post of medical officer of health, was visited by an extensive epidemic of *measles.* The *estimated population* was 61,664, composed chiefly of artisans and brewery employés, and the houses occupied were mostly four-roomed and six-roomed. The Notification Act had been applied to measles since Dec. 1st, 1893. There had been three biennial epidemics of measles during the last six years. In the epidemic of 1898 there were 2048 known cases and 31 deaths, giving a case fatality of only 1·5 per cent. and a death-rate of 0·60 per 1000. It was probable that 95 per cent. of all the cases were notified or came to the knowledge of the sanitary authority. The ratio of children under school age (called babies) to infant school children (called infants) attacked was from 80 to 100. The epidemic first started through a tea-meeting and *entertainment,* and two infants in arms were the first cases in houses where the mothers but not the babies had been to this meeting. Later two Sunday-schools were clearly responsible for the distribution of the disease to two other districts. Amongst babies who were the first cases in houses, 26 per cent. of the cases occurred in houses where there was a case next door, 11½ per cent. where a case was two doors off, and 5½ and 8 per cent. where cases were three and four doors off; and amongst infants the respective percentages were 13, 10, 6, and 6½. The conclusions deduced were (*a*) that measles first introduced into a district through an infant Sunday school or day school at once spread rapidly in that school and district, and that the degree of rapidity and the extent of the spread were inversely proportionate to the frequency of epidemics unless *early* closure were carried out; (*b*) that the disease first introduced into a district by means of isolated cases did not spread to any extent until the infant school became infected; (*c*) that Sunday schools were an important factor in the distribution of the disease; (*d*) that the babies might be infected to a slight degree and under certain circumstances before the infant school was infected; but the greater proportion were infected a short time after the school; and (*e*) that the danger of house-to-house infection was a serious one amongst the baby class, and that in proportion to the proximity of an infected house (where houses were in close contact) so was the danger of infection. In all cases a school was closed within three days of its being known to be "a source of infection," as were the Sunday schools in the same districts. The incidence in the boys' and girls' schools in districts where there had been biennial epidemics was practically *nil;* but where there had been no real epidemic for at least six years the incidence amounted to as much as 20 per cent, in one case, of those in average attendance. The conclusions come to on school closure were (1) that in nearly every instance this measure was carried out too late; (2) that good results could be obtained, not only amongst infants but babies also, when schools were closed at once without waiting for the infant department to become "a source of infection"; (3) that when an epidemic occurred every two years the infant schools only need be closed, but with longer intervals it became necessary to close the boys' and girls' schools also; (4) that sanitary authorities should have the same power of compulsory closure over Sunday schools as over day schools; and (5) that the power to close schools for a short period—one or two days—on account of a threatened epidemic, especially of measles, would be a most useful measure. For "information of the presence of measles," compulsory notification under the Notification Act was the chief source, but should be supplemented by other methods.—Dr. R. Dudfield, Mr. Shirley Murphy, Dr. W. A. Bond, and the President took part in the discussion.

HARVEIAN SOCIETY OF LONDON.—A clinical evening of this society was held on March 15th, Dr. W. H. Lamb, the President, being in the chair.—Dr. Cautley showed a female infant who had recovered from an attack of Basal Meningitis of three months' duration. The child was the third in the family, the others being healthy. She came under treatment on Nov. 23rd, aged 10 months, with a history of a measles rash on Nov. 4th and a fall on the head on Nov. 16th. Drowsiness, restlessness, and irritability were noted on the day after the fall, and on the next day stiffness of the muscles of the neck, retraction of the neck with pain on movement, frequent pulse, fever, and constipation. The course of the illness was characterised by the above symptoms, frequent vomiting, tache cérébrale, retracted abdomen, screaming attacks, and a hectic type of temperature ranging between 98° and 104° F. For two months no improvement took place, but in the course of another month the fever and symptoms subsided, with temporary relapses, and after Feb. 11th the temperature remained normal. During the illness the weight diminished from 14 lb. 8 oz. to 11 lb. 5 oz. It was rapidly regained during convalescence, a gain of 4 lb. taking place in 17 days. The child now weighed 15 lb. 10 oz. and was apparently quite well.—Dr. Cautley also showed a case of Congenital Infantile Paraplegia occurring in a boy, aged 21 months, the eighth child of a very healthy family, all the other children being alive and healthy. He was born at full time, labour being easy and not instrumental. He was entirely breast-fed for a year and partially so for another six months. Teething began at the eleventh month and now eight teeth were cut. He was quite healthy until he had an attack of diarrhœa and vomiting, followed by a fit, last October. At present he was a large and well-nourished boy with the exception of the lower limbs. These latter were small and ill-developed. The patellar and plantar reflexes were much exaggerated. He had never crawled, could not stand, and raised himself with much difficulty into the sitting posture which he maintained with ease. He appeared to be mentally deficient. The weakness of the limbs was only noted in October, but had almost certainly been in existence since birth.—Dr. Macevoy showed a boy, three and a half years of age, suffering from Little's Disease (cerebral diplegia). He was born prematurely (at the seventh month), delivery being instrumental, and for some minutes he was in an asphyxiated condition. The presentation was placental (placenta prævia). He had severe rachitis between eight months and 14 months; he could not sit up before the age of 18 months; and only stood on his legs when two and a half years of age. His gait since then had always been typically spastic and ataxic. He frequently fell. Rigidity, though worse in the legs, was present in the arms and neck. He had athetosis and incoordination of the arms, with athetotic movements of the feet and head. The plantar reflex gave an extensor reaction; the knee-jerks were brisk, but occasionally were not obtained on account of the rigidity. There was no clonus. The boy's general development was good and he was fairly intelligent, but could only say a few syllables.—Dr. Leonard Guthrie showed a lad, aged 18 years, whose symptoms were regarded as due to tumours either in the neighbourhood of the left optic thalamus or in the right cerebellum.—Dr. Alfred Eddowes showed the following cases: (1) A girl presenting a single Patch of Lupus on the left side of the face and a Patch of Impetigo on the opposite side; (2) a case of Lupus Erythematosus of the Scalp of 12 years' duration in the form of two perfectly symmetrical patches about three inches long and nearly two inches wide running vertically down the sides of the scalp about an inch behind the ears; and (3) a girl recovering from Leucodermia whose back three years ago was of a dull yellow colour with numerous white patches on it, but the pigmentation of the whole back was now practically normal.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A meeting of this society was held at Owens College on March 14th, Mr. W. Thorburn, the President, being in the chair.—Dr. Powell White showed specimens of Bacilli Diphtheriæ showing Branching. They were obtained from a culture on agar-agar 48 hours old. The culture was remarkable for the large size of the club-shaped forms, some of which measured as much as 40 μ in length. These large forms, as well as those of more normal size, showed well-marked true branching, the branches being clubbed at the extremities. Sub-cultures showed ordinary forms of the bacillus only.—Dr. J. R. Carver showed several specimens of Non-typical Diphtheria Bacilli which he had met with in the examination of specimens sent up by various sanitary authorities. He showed bacilli of great length interlacing with each other and showing doubtful branchings, which seemed to merit the term "streptothricial" bacilli. The long forms disappeared on sub-culture. Other specimens showed bacilli with enormous pear-shaped heads; and in another the sheath of the bacillus was very faintly stained, while the protoplasm was collected into a chain of fine granules giving the appearance of an encapsuled streptococcus. He thought that the greatest difficulty in the identification of the bacillus was in doubtful forms of the short bacilli, especially when these somewhat approached the bacillus coli type. He had found that pneumococci in process of division might resemble a double club-shaped bacillus and show a certain amount of meta-chromatism.—Dr. M. Cowen and Dr. David Orr made a preliminary communication on the Morbid Anatomy of General Paralysis of the Insane and illustrated their remarks with microscopical specimens. They described the changes in the nerve cells of the cortex, pons, medulla, and cord, in the medullated fibre of the cortex and cord, and the neuroglia and vessel changes in the cortex. They pointed out that the cell changes—i.e., the chromatolysis—was of a slow chronic nature, invading more especially the perinuclear region, and was associated with marked increase of the cell pigment, so bearing a striking similarity to the senile involution changes described by Marinesco. In the cord they found the damaged fibres almost entirely confined to the crossed pyramidal tracts with a few scattered morbid fibres in the posterior, lateral, and anterior pyramidal tracts. Neuroglia proliferation and hypertrophy were demonstrated especially in the white matter, sub-pial, and innermost layers of grey matter. Peri-arteritis of more or less degree was shown to affect the arterioles in every case. They were of opinion, from their investigations in early general paralysis, that the nerve cell was the first to degenerate and later the tangential and other medullated fibres.—Dr. E. S. Yonge showed specimens illustrating Acute Phagedæna of the Nose and Face. The patient, a man, aged 26 years, gave a history of alcoholism and syphilis and was suffering from phthisis. Phagedænic ulceration began in the roof of the mouth, immediately behind the incisor teeth; it spread into the nose and in a few days completely destroyed the soft parts of that organ. The right side of the face and the right eye then rapidly became gangrenous and the air-sinuses were invaded. Finally, the process involved the left side of the face and the left eye. Death occurred one month after the onset.—Dr. R. B. Wild showed preparations from a case of Cancer of the Body of the Stomach, in which the orifices were unaffected, but a large part of the anterior wall, lesser curvature, and posterior wall was occupied by a firm scirrhous growth. One nodule of the growth within the stomach was prominent and presented a horny degeneration of the epithelial cells. The liver presented several secondary nodules showing similar horny changes—Other preparations were shown as card specimens.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on March 9th, Dr. A. Newsholme, the President, being in the chair.—Dr. J. Priestley, medical officer of health of Lambeth, read a paper on Area Condemnation under the Housing Acts, Part I., which, though simple enough in theory, was in practice tedious and costly, while during the long delay the sanitary condition of the area went from bad to worse. He held that in a condemned area the majority of the houses were as a rule capable of repair, a minority only being wholly unfit for human habitation, and he thought that a system of vigilant house-to house inspection with abatement of nuisances and enforcement of repairs, the few houses only whose conditions were irremediable being demolished one at a time, with no wholesale displacement of the population, was in every way to be preferred. He had constantly carried it out in his district, which he thought would compare favourably with an adjacent one where areas had been ruthlessly condemned. Such displacement of the population served but to create overcrowding with all its concomitant evils in other districts which soon became converted into slums. It was not possible to provide for an equal number of persons on the same area under improved sanitary conditions, and the better houses springing up at higher rents than the labourer could afford were promptly appropriated by the thriving artisans. He believed that more good could be effected by Part II., by enforcing the provisions of the Public Health Act, by constant house-to-house inspection, and by substituting when these means failed house condemnation and house demolition for the condemnation and clearance of areas.—Dr. F. J. Allan (Strand) said that whatever might be the case in Dr. Priestley's districts the conditions prevailing elsewhere were such that the application of Part II. of the Housing Act, or the clauses of the Public Health Act bearing on the structural and sanitary conditions of houses, might be most unsatisfactory, if not futile. He could not understand what Dr. Priestley meant by his statement that in "unhealthy areas" the majority of the houses were capable of being made habitable.—Dr. A. M. Chalmers (Glasgow) gave an account of the practice of the authorities in his city, a combination of action under Parts I. and II. He admitted that there were circumstances under which Part I. alone could be of use, but it should not be adopted without necessity, for the mere clearing of the area cost on an average £50 per head of the displaced population.—Mr. Shirley Murphy maintained that Dr. Priestley had totally misconceived the purposes of Part I. Wholesale clearances were unavoidable with slum property, courts, alleys, and back-to-back houses.—Dr. J. F. J. Sykes and the President also took part in the discussion.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY.—*A meeting of this society was held on* March 8th at 20, Hanover-square, the President, Dr. Ivor Murray (Scarborough), being in the chair.—The discussion on the Treatment of Nervous Diseases and Affections by Baths and Climate which was introduced by Dr. Harry Campbell on Jan. 26th was resumed.—The President read a synopsis of the previous discussion.—Dr. Leonard Williams in reopening the discussion said that inasmuch as the graver forms of nervous disease, such as tabes, general paralysis of the insane, and the like, were essentially diseases of city life it was reasonable to suppose that better results were to be obtained by removing patients from such surroundings than by drug treatment alone. He instanced cases to illustrate the good effects of climatic treatment in these affections and related a case of epilepsy which had apparently been very favourably influenced by a soothing climate.—Dr. Alexander Morison stated that the cure of organic nerve lesions by climatic and balneological treatment might be excluded from discussion. In this respect the scope of treatment in general applied to these agencies in the same measure as to other means rationally used.—Dr. W. S. Hedley considered that the health resort plays very much the same part in diseases of the nervous system that it does in other classes of disease.—Dr. Knowsley Sibley said that for some years he had been accustomed to treat various forms of nervous diseases by the local application of dry hot air and generally with undoubted success. The cases which did well were insomnia, epilepsy, many forms of neuralgia and neuritis, together with various paralyses *of hysterical* origin, so also chorea was especially *amenable*, the movement frequently quite ceasing, while the limb was under treatment. Ménière's disease appeared also to be benefited. Old-*standing*, cases *of*, *paralysis*, especially those caused by lead palsy and those of traumatic origin, often improved. He had *been disappointed* with the result of this treatment in marked cases of tabes, *paralysis agitans*, and writer's cramp, but he had never seen any harm arise from it.—Dr. Harry Campbell remarked that this was the first time that a discussion of this kind had *taken place* in this country. We had relied too much upon drugs in the treatment of nervous diseases, being in this respect much behind continental physicians.—Dr. R. W. Felkin, Mr. G. H. Thompson (Buxton), and Mr. Shirley Jones (*Droitwich*) also took part in the discussion.—Dr. William Bain (Harrogate) read a paper entitled "The Effects of Luminous and Heat-rays on the Local and General Temperatures."

BIRKENHEAD MEDICAL SOCIETY.—A meeting of this society was held on March 6th, Mr. H. Nazeby Harrington, the President, being in the chair.—Dr. W. R. Dalzell read a paper on General Paralysis of the Insane. After briefly reviewing the history of the affection and describing the symptoms of various types met with in asylums and in general practice he passed on to the consideration of its etiology and pathology, giving as the chief factors in its etiology (1) over-exertion, (2) syphilis, (3) alcoholism, and (4) excessive venery. As to distribution it was found all over the civilised world, though it occurred chiefly in the great industrial centres and seldom in the rural districts. It occurred much more frequently in males than in females and it was essentially a poor man's disease, though it was also found in the higher ranks of life. Passing to diagnosis Dr. Dalzell enumerated the following affections amongst others which might be confounded with it, giving the differential diagnosis in each case: (1) acute recent mania, (2) alcoholic paralysis, (3) pseudo-general paralysis, (4) syphilitic brain disease, (5) lead paralysis, (6) senile dementia, (7) epileptic paralysis, (8) primary dementia, and (9) locomotor ataxia. As to prognosis his experience was that nearly all cases ended fatally, usually through some intercurrent disease—the chief of which was phthisis—within three years. With regard to treatment there was nothing known which would arrest the disease and one had to be content with general hygienic measures, the removal of all nerve excitants, and the assistance of hypnotic and nervous tonics.—A discussion on Medical Politics took place and the following resolutions were unanimously passed:—

1. *Medical Acts.*—That in the opinion of this society the Medical Acts require amendment especially in regard to illicit practice, death certification, and the Inebriate and Lunacy Acts.

2. *Contract practice.*—That in the opinion of this society in contract practice there should be a minimum rate of 6s per member per annum, and this society condemns the practice of canvassing in connexion with medical clubs.

3. *Medical charities.*—(*a*) That in the opinion of this society there is considerable abuse in connexion with medical charities, and it is *desirable that the medical profession should be directly represented on* the committees by which they are managed. (*b*) That the staffs of the various hospitals be requested to combine in getting a visitor appointed to inquire into the circumstances of patients applying for relief in order to prevent such abuse.

4. *Midwives question.*—That in the opinion of this society it is not desirable that midwives should be registered according to the provisions of the Bill at present before the House of Commons.

5. *Direct representation.*—That in the opinion of this society it is desirable that general practitioners should have a *larger representation* on the General Medical Council.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 7th, Dr. H. Michie, the President, being in the chair.—Dr. H. Handford showed two cases of Nervous Disease following Typhoid Fever. Both were cases of young men, in one of whom symptoms of lateral sclerosis with increased reflexes and the typical spastic gait, &c., were observed; in the other case the signs and symptoms were those of a patient with tabes dorsalis, knee-jerks being abolished and ataxia existing. Both cases were on the high road to recovery when shown, but there still existed indications of the above-named diseases. The interest of the cases lay in their extreme rarity and in their close simulation of the above-named diseases, from which they differed, however, in that they were recovering.—Dr. J. Mackenzie read a paper on Notes of Cases of Diphtheria occurring in Private Practice treated by Antitoxin. Dr. Mackenzie first classified the cases into groups in accordance with the anatomical situation of the disease; in all there were seven such groups. The number of the cases treated with the serum was 31, and they were the severest cases occurring in Dr. Mackenzie's practice, it not being his habit to inject serum in mild cases. In most, or at least in many, of the cases the disease had existed for nearly a week without being seen. In the whole 31 cases so treated there occurred but two deaths, giving a mortality of just above 6 per cent. Respecting one group of three cases, however, Dr. Mackenzie admitted that there was a possibility that the disease was not true diphtheria, but perhaps a simple acute laryngitis. The patients all recovered, but they were all given the serum. Excluding those three cases there were 28 cases of true diphtheria, and many were of a very severe nature, with a death-roll of two, giving a mortality of 7·1 per cent. only.—The paper was discussed by the President, Mr. R. Woods, Mr. J. S. Bolton, Mr. J. Thompson, and Mr. W. M Willis.—Mr. R. C. Chicken read an account of a New Method of performing Hysterectomy which he had devised for Prolapse of the Uterus, which had for its object not merely the removal of the extruding organ but the formation of a support to the pelvic floor.

Hunterian Society.—A pathological meeting of this society was held on March 14th, the President, Dr. Dundas Grant, being in the chair.—Dr. Glover Lyon showed a Heart (lent by Dr. Casterton Smelt) the Aortic Valve of which was Incompetent apparently through Extensive Fenestration. This heart had beaten as a rule between 30 and 40 times a minute for 20 months before death, sometimes at a much slower rate.—Dr. Frederick J. Smith showed a specimen of Pachymeningitis Hæmorrhagica, a Large Malignant Growth of Kidney Occurring in a Child aged ten months, Extensive Basic Meningitis with a Small Patch of Old Tubercle of the Lung, Abscess in the Lung and Brain in which there was absence of fœtor, and Adherent Pericardium with old Endocarditis which had presented no signs usually said to indicate adherent pericardium.—Dr. Dundas Grant showed a Nasal Polypus which had occupied the whole naso-pharynx. This had been removed under a general anæsthetic, a course which Dr. Grant recommended in such cases.—Remarks were made upon the cases by Dr. A. Adams, Dr. T. R. Andrews, Dr. W. H. Kelson, Dr. Glover Lyon, Dr. D Ross, Mr. J. H. Targett, and the President.

Æsculapian Society of London.—A meeting of this society was held on March 23rd, Mr. A. W. Galloway, the President, being in the chair.—Dr. Thomas G. Stevens read a paper on the Early Diagnosis of Uterine Carcinoma in the course of which he described the different varieties of malignant growth found in the uterus and emphasised the value of a microscopical examination of growths. He thought among the out-patients of a hospital suffering from uterine malignant disease that not 15 per cent. when first seen were at a stage early enough to justify operation. The paper was illustrated by a series of microscopic sections which included one of deciduoma malignum.

Southport Medical Society.—A meeting of this society was held on March 14th, Dr. C. Pinkerton being in the chair.—Mr. Reinhardt Anderson mentioned a case of Perforated Gastric Ulcer on which he had operated with successful result.—Dr. Percy Ashworth read an interesting paper on the Treatment of Cardiac Failure, and a discussion followed.

Cornwall Nursing Association.—The annual meeting of the Cornwall County Nursing Association was held at Truro on March 16th under the presidency of the Earl of Mount Edgcumbe. The report stated that 14 nurses were now employed in various districts, exclusive of those districts which were supplied by the Queen's nurses. 1030 patients had been attended at their homes, 121 being midwifery cases, and 29,155 visits had been made by the nurses. The expenses for the year amounted to £432 (an increase of £185 over the amount expended in 1898). The expenditure exceeded the income by £100 and the committee had drawn £100 from their capital. The capital is now only £700, and the committee make an urgent appeal for more funds. Thanks were awarded to the medical men in the various districts whose assistance so largely contributed to the success of the association.

Reviews and Notices of Books.

Darwin and Darwinism, Pure and Mixed. By P. Y. Alexander, M.A., LL.D. London: John Bale and Sons. 1899. Pp 346. Price 7*s.* 6*d.*

The author of this volume devotes himself chiefly to a series of detached criticisms upon the views of Darwin, particularly directing attention to that naturalist's occasional changes of opinion as shown by contrasting the earlier utterances of "The Origin of Species" and some other works with expressions to be found in his later published biography. Well, no one doubts that in details there was much development of view in the mind of the illustrious author of the theory of natural selection. So far Dr. Alexander has re-discovered the perfectly well known. Dr. Alexander disconcerts us somewhat by his intense admiration of Artemus Ward. We fully share that admiration, but the dicta of that philosopher are not convincing when applied to the natural phenomena otherwise treated with gravity by the author. "You pays your money and you takes your choice" is a phrase which occurs at least twice in the volume and is nowhere explanatory. He begins by instancing the fact that there appear to be some well-established examples of change in structure due directly to the environment to which more weight was allowed by Darwin in later years than formerly when he was disposed to solve all problems with his newly invented key. At the same time, in the animal world at any rate, the examples of such change are not very abundant. The author of the volume before us reminds us of a few well-known instances, such as the brine-pool crustacean and the metamorphosis of the Axolotl into the purely terrestrial Amblystoma. But when all are told only the merest corner of the complex edifice of fact and argument erected by the genius of Darwin is injured. *Apropos* of this same effect of surroundings Dr. Alexander considers the butterfly and the moth. There is apparently no doubt that light does exercise some influence on the development of bright colour; and so, as the author justly points out, do heat and cold. But it is impossible to generalise widely and to arrive at the conclusion that "the brighter and more constant the light that falls on these forms the more splendid they become through complicated chemical processes set up by the light's action." Here, indeed, the author suffers from a too partial survey of insufficient fact. He is by no means alone in this, and many of his opponents conspicuously select some facts and ignore, or are unacquainted with, others. Anyone who has attempted to deal with large subjects, such as the influence of environment, knows well that the enormous amount of material which should be sifted before formulating conclusions is really too great to be grappled with by a single person. To write such books a specialist in every group is required.

It does not appear to us that Dr. Alexander has scored a point in his criticism of the origin of species from "fortuitous" or any kind of variations. He states that, it being admitted that variations occur without any natural selection, the origin of species is solved, for there we see the species ready made without the necessity of waiting for selective influence. That at any rate is how we understand a rather complicated argument on page 65. But this is really the whole gist of the matter, the whole quarrel between Dr. Alexander and those whom he attacks. No one would term, for example, an albino mole as a newly formed species of mole, unless the individuals so coloured bred true and produced in the main moles with this marked colour difference from their ally. On this or any other variation it is asserted a species may be formed by, as it were, fixing the variation. The author goes on to remark that variation "come into existence in an absolutely unexplained and even unrecognised manner"; and here we can cordially agree with him. That is indeed the crux of evolutionists, and until that problem is grappled with and solved there is but little hope of a consistent theory of the organic world. "Survival of the fittest" is a phrase which has to the full the disadvantages which always encumber such neat and epigrammatic sentences. In criticising it Dr. Alexander is following in the footsteps of many predecessors.

No one doubts for a moment that when a whale engulfs a shoal of herring the fate is indiscriminately dealt out to them, just as the fall of the Tower of Siloam crushed both the just and the unjust; indeed, it has been suggested with some acuteness that survival of the fittest comes to much the same thing as survival of the survivors. Dr. Alexander urges an interesting piece of observation in support of a contention that it is not always the apparently "fittest" that actually survive. "Certain flowers that have abundant nectar are chosen by certain birds for their honey. I have observed by watching them and then examining the heads or clusters after the visits of the birds that all the stronger cups had been mutilated and cut off, and that the young and weakly cups without nectar or a very little of it were left—systematically left." Now this observation, though undoubtedly interesting, is not sufficient. Dr. Alexander does not tell us either the locality of his observations or the kind of birds that perpetrated the damage. The omission is important, for the birds may have been sparrows and their attacks delivered in a country new to them as sparrows. And in that case we cannot lay any stress upon the observation since the most lukewarm adherent of the theory of natural selection would freely admit that time is required for an adjustment to new conditions. Natural selection in fact, to use the commonly used and necessarily crude personification, is not prepared for the victory which has been gained over natural processes by the coming of man into the world.

There is much argument and disputation in Dr. Alexander's book with a great deal of which we cannot agree; and there is also a certain amount of slaying of the slain and the toppling over of men of straw. There is also much that is readable and interesting. Dr. Alexander has not undermined our belief in a great deal of Darwinism and, indeed, he does not profess to do more than deal with "certain lines only of discussion." But we do not regret having spent some time with his book.

An Elementary Course of Practical Zoology. By the late T. JEFFERY PARKER, D Sc, F.R.S., Professor of Biology in the University of Otago, New Zealand, and W. N. PARKER, Ph D., Professor of Zoology at the University College of South Wales and Monmouthshire With 156 illustrations London Macmillan and Co Limited. 1900. Pp. 607. Price 10*s*. 6*d*.

THE manual before us is written by the sons of the talented and indefatigable worker Mr. William Kitchin Parker, whose admirable descriptions of his embryological researches, illustrated by his own pencil, on the morphology of the skull in the several classes of the vertebrata fill so many pages of the Transactions of the Royal Society and of the Linnean Society. The treatise was to be a conjoint one, but by the untimely death of the elder brother, Professor T. J. Parker, the labour of its production has fallen on the shoulders of Professor W. N. Parker, some of the illustrations being drawn by Mr. M. P. Parker, the rest being taken from the Elementary Biology of Professor T. J. Parker.

The plan adopted by the authors differs from that pursued in the similar text-books of Campbell, Nicholson, Gibson, Chalmers, Mitchell, Bidgood, Thomson, and Davis, who commence by familiarising the student with the simplest organisms, leading him by degrees to the more complicated, and on the other hand agrees with that followed by Wells and Davies, Lloyd Morgan, and others, who prefer to exercise the faculty of observation in the first instance on some conspicuous and familiar example of the higher orders, placing before the learner some specimen which is easily procurable and in which the steps of the dissection described in the text can be repeated without difficulty. Both methods have their advantages. Those who commence with the lower organisms can hardly do so without some preliminary education in the manipulation of the microscope and its accessories, section-cutting, staining, and mounting, yet they obtain correct notions of structure; whilst teachers who select a vertebrate for their first object-lesson furnish material the description of which can be easily followed by the members of the class, though these may be a little uncertain as to the nature of nerve and muscle and gland. In the present "Course of Practical Zoology" either plan may be adopted by the reader, for nearly the first half of the book is occupied with a carefully drawn up description of the Anatomy of the Frog, from the pen of Professor T. Jeffery Parker, whilst the remaining and rather larger portion commences with an account of the amœba, which is succeeded by descriptions of the hæmatococcus and euglena, paramœcium, opalina, and vorticella; the hydra and bougainvillia; the earthworm, crayfish, fresh-water mussel, amphioxus, and the dogfish, the series terminating with the rabbit. In each case a very good description of the animal is given, with excellent illustrations, which is followed by "practical directions" as to the mode of conducting the dissection. The work will be found serviceable to the upper classes of schools where natural history is taught and to classes for elementary biology in medical schools.

LIBRARY TABLE.

The Flowering Plant. By J. R. AINSWORTH DAVIS, M.A., F.C.P. Third edition. London: Charles Griffin and Co., Limited. Pp. 195 Price 3*s* 6*d*.—This is the third edition of a well-known little book designed to illustrate the first principles of botany. It has undergone careful revision and a number of new illustrations have been added together with a chapter on ferns and mosses This chapter is an important addition, and although in a sense it makes the title of the book somewhat of a misnomer it will materially add to a clear comprehension of the life history and classification of phanerogams. There is also an appendix on practical work dealing with the description of plants—their anatomy, physiology, and histology—and this, too, will be found of immense help to the student. The arrangement of the subject matter is excellent and most of the plants mentioned are easily accessible to the student Too many technical terms have perhaps been used and the method of explaining them in the text is not likely to attract the beginner in this department of biology. The plan of giving the Latin or Greek derivation in brackets would have been less likely to make the reading tedious. Otherwise the book, which is crammed with information, is a good one

The Excretion of Urea by the Skin in Health. By C. C. EASTERBROOK, M A, M B. Edin., Assistant Physician, Royal Asylum, Edinburgh Reprint from the *Scottish Medical and Surgical Journal*, February, 1900. Pp 20.—The author, struck by the amount of urea secreted by the skin in artificial perspirations in the treatment of uræmia, instituted experiments on himself on the amount of urea excreted during exercise while on a fixed mixed diet and concludes that the statements in the current text-books of physiology considerably underestimate the capacity of the skin for the elimination of urea in health and that the excretion of urea by the skin at once rises as soon as perspiration sets in and remains high as long as the skin acts freely, to an extent sufficient to lessen distinctly the output of urea in the urine.

Unwritten Laws and Ideals. Edited by E. H. PITCAIRN. London: Smith, Elder, and Co. 1899. Pp. 358. Price 7*s.* 6*d.* —The editor's idea in putting forth this book was, as he says in his preface, that if he could persuade representative men of various professions to set forth the unwritten laws by which those professions are governed and their ideals in regard to them, a useful and interesting book might be compiled. Mr. Pitcairn has succeeded both in persuading his representative men and in compiling the interesting book. The "professions" include the diplomatic service, the Houses of the legislature, the services, the divisions of the three faculties of divinity, law, and physic, vice-chancellors, schoolmasters and schoolboys, banking, music, art, and architecture. We naturally, as medical journalists, turned to the article dealing with our own profession which is written by Mr. Brudenell Carter. And a very excellent article it is both in matter and style, although on page 210 there is a curious slip in a date. The year in which the Royal College of Surgeons of England obtained its Charter sanctioning the creation of Fellows is given as 1884, whereas, of course, it should be 1843. But could there be any better summation of the ideals of the medical profession than these words on page 251? "The unwritten laws of the medical profession are to do as its members would be done by, to bring adequate skill and knowledge to the accomplishment of their work, to be true and just in all their dealings, and in the words of Sir James Paget, 'neither to neglect their duties for the sake of ease nor to abuse their opportunities for the sake of gain.' They ask in return that they themselves should be treated with justice and fairness." Of the other essays in the book it scarcely becomes us to speak critically, written as they are from a technical point of view by the several experts concerned, but we may make an exception as to the admirable essay upon the clergy written by the Rev. W. B. Trevelyan. The essay does not deal with theology, but mainly with the relations of the clergy to their own flocks and to those of other clergy. Now the medical profession and that of the clergy are alike in one way. The members of both are men to whom their fellows confide their most private sorrows. Both professions have to give advice upon the most intricate and delicate questions, both professions are bound by every moral law to keep the knowledge gained in the exercise of their calling as strictly confidential, and for the credit of humanity, be it said, such confidence is rarely if ever abused. But with all this both the clergy and the members of the medical profession are as a city set on a hill. Their actions are in the sight of all men and the sins of a black sheep in either flock are visited whether justly or unjustly upon all his fellows. The clergy may study with advantage Mr. Brudenell Carter's remarks upon the duty of one medical man to another, while section 5 of Mr. Trevelyan's essay will bring home to medical men, perhaps all the more as something written by one outside the medical profession and for members of another calling, their own duty to their brethren engaged in the arduous toil of everyday practice.

The Literary Year-book, 1900. Crown 8vo, 420 pages, cloth limp. Price 3*s.* 6*d.* London: George Allen.—The fourth issue of this useful little book, which is edited by Mr. Herbert Morrah, is divided into two distinct parts. The first deals historically and critically with the Literature of the Year 1899; the second provides a large amount of information arranged in a convenient form upon various matters of interest to all engaged in literature. Part I. includes a retrospective review of the literary events of the past year and a series of articles on the notable books of the year. These critical reviews are contributed by representative men of letters, and will all be found worth reading, though some of the writers, notably Mr. W. E. Henley, Mr. Joseph Jacobs, Mr. T. Herbert Warren (the President of Magdalen College, Oxford), Mr. A. T. Quiller-Couch, and Mr. G. W. E. Russell have been happier than the others. This division of the book also includes an article on the Book Sales of 1899, by Mr. Frank Rinder, which will be of great practical interest to systematic book-buyers, among whom many medical men may be found. Part II. contains, alphabetically arranged, a full list of authors with the names of their books published during 1899, the prices, and the publishers' names. It also contains alphabetical lists of illustrators of books with full particulars of books illustrated by them during the past year; lists of the books and plays published in 1899; and a great deal of trade and technical information upon printing, illustrating, royalties, &c. We recommend the book cordially to all our readers who require a compilation of this sort; it is careful, practical, and as far as possible complete.

New Inventions.

A TENT FOR THE OPEN-AIR TREATMENT OF TUBERCULOSIS.

MR. VICTOR H. NORMAN of Dene Side, Great Yarmouth, has submitted to us a small working model of a revolving tent for the open-air treatment of tuberculosis, originally constructed for the use of a patient under the care of a medical man in Norwich. A tent of the usual size for one patient has a rectangular wooden floor measuring five feet by six feet and supported on four small wheels, one near each corner; the floor is pivoted centrally on a circular wooden base of rather more than its own diameter, upon which it revolves freely by means of the wheels and can therefore be easily turned in any direction according to the position of the sun or the state of the weather. Dampness is completely avoided by the base being raised somewhat above the ground by wooden battens on the under side. The tent is covered on three sides and the top with light green canvas (best Willesden rot-proof) made all in one piece and drawn over a four-sided wooden frame fitted together in a simple manner with ordinary screws. The top is flat and slopes from a height of six feet in front to a height of five feet six inches at the back. The open front is provided with a moveable sun-blind. The price of a tent of the above dimensions is £7 10*s.* None of its parts are likely to get out of order and it is apparently well suited for its purpose. During windy weather it might require to be held by ropes and pegs in the usual way.

UNIVERSITY OF CAMBRIDGE.—The following degrees in medicine were conferred on March 15th:—*M.D.*: E. A. Peters, Caius. *M.B.*: H. N. Clarke, Trinity; J. A. Nixon, and W. Tyson, Caius. *M.B. and B.C.*: F. T. Talbot, King's. Dr. H. K. Anderson and Mr. W. B. Hardy have been appointed Demonstrators in Physiology.—The new arrangement establishing a formal connexion between the University and Addenbrooke's Hospital was ratified by the Senate on March 15th and by the Court of Governors on March 19th. It will come into force without further delay.

ROYAL HOSPITAL FOR WOMEN AND CHILDREN, BRISTOL.—The annual meeting of governors and others interested in this institution was held on March 17th under the presidency of the high sheriff (Mr. G. A. Wills). The medical report stated that the out-patients numbered 4978 and that 690 children and 45 women were admitted during the year. 443 dental cases had been attended to. The financial statement showed that the ordinary expenditure of the year amounted to £4422 and the ordinary income was £3657, leaving a deficiency of £765. The past year commenced with an adverse balance of £2811, towards which £889 had been received by special donations, and £1200 had been transferred from the legacies account, so that at present there is a total deficit of £1487.

THE LANCET.

LONDON: SATURDAY, MARCH 31, 1900

THE history of the surgery of the stomach resembles that of *the surgery of many other important organs of the body* it is a record of gradual progress from the slightest surgical interference to operations of the greatest magnitude and severity, even to *extensive resection* Time was when the most that a surgeon dared to do was to make an opening into a healthy stomach to remove a foreign body, or perhaps he might be induced to make a permanent aperture into the stomach in a case of malignant stricture of the œsophagus The results however, were hardly such as to encourage surgical treatment, for the mortality was *exceedingly heavy* This was *attributable in part to* sepsis, but in no small degree it was due in the case of the operation of gastrostomy to a very natural reluctance on the part of physicians to call in surgical aid until the patient was almost dead from exhaustion Naturally the results in such cases were nearly uniformly bad and the delay in operation tended thus to increase the hesitation to permit any operation to be performed Professor MAYO ROBSON has recently delivered three Hunterian Lectures at the Royal College of Surgeons of England on the most interesting subject of the surgery of the stomach and the concluding lecture of the series appeared in the *issue of* THE LANCET *of* March 24th From these lectures we learn the present state of the surgical treatment of the disorders of this organ Large portions of the stomach may be excised or even the whole may be removed with no very great mortality, and in successful cases with wonderfully little effect on the patient's digestion The stomach hardly occupies in our present opinion so important a place in digestion as it formerly held We know that it is rather a preparer for the exercise of the digestive powers of the pancreas than an active digestive agent itself and that one of its functions is to render innocuous many of the micro-organisms which enter with the food So that we can understand to some extent the small amount of interference with digestion produced by even considerable resections of the stomach There are, moreover, many morbid gastric conditions, not due to the presence of malignant growths in which drugs and dieting are of no avail and the patient, being unable to eat and unable to work, sinks into a condition of valetudinarianism We now know that many of these cases are due to a definite lesion, such as an adhesion of the stomach to a neighbouring organ, or to cicatricial narrowing of the pyloric orifice by which the egress of the food from the stomach is prevented or an "hour glass" condition may be present in which the organ is constricted in the middle, so that it consists of two distinct loculi connected by a narrow channel In all these conditions medicinal treatment is almost useless and though extreme care in the quantity and quality of the food taken may suffice to keep the patient alive yet his very existence is to him a perpetual burden In no operation, it may fairly be said is the beneficial effect of surgery more strikingly shown By the division of the restraining adhesions the stomach is enabled to carry on its muscular movements unhindered, by enlarging the narrowed pylorus by the Heineke Mikulicz operation of pyloroplasty, or by performing some one of the many varieties of gastro enterostomy the surgeon enables the dilated stomach to empty itself of its accumulated contents and the distressful vomiting ceases at once When the hour glass contraction is present the two cavities into which the stomach is divided are made to communicate freely and all the untoward symptoms disappear *But that is not all, in every one of these cases* wasting has occurred often to an alarming extent, the process may have been long and the emaciation gradual, but ultimately the patient has become reduced to a mere shadow of his former self After the operation, should it prove successful, all is changed a steady gain in weight follows, and cases have even been recorded in which the weight of the patient *has doubled Many of these cases to which we have* referred are caused by the healing of former ulcers but surgery is also of value in some cases in which the simple gastric ulcer is still present In such as these, it is hardly needful to say, medicine can do much but in many instances surgery can do more The milder cases of ulcer will heal readily under medicinal treatment with care in dieting They do not require any surgical interference, but if the ulcer should prove intractable should it extend in area and especially in depth, or, lastly, should perforation of the gastric wall occur, then the aid of the surgeon must be invoked For the chronic ulcer a *gastro-enterostomy may* be performed, and by the rest which the stomach gains the ulcer is enabled to heal In cases of perforation except when previously formed adhesions limit the effused gastric contents, recovery without an operation cannot occur Valuable time may be lost in the administration of opium and the application of fomentations, for the statistics in Professor MAYO ROBSON'S lectures clearly show that the mortality after operation for perforation of the stomach depends in great part on the interval that elapses between the occurrence of the perforation and the operation though the condition of the stomach as to fulness has also much to do with the result

For cases of hæmorrhage from the gastric wall surgery is only of distinct value in the less acute forms, but in these the results hitherto attained fully justify recourse to surgical treatment in some cases

There are certain cases also of non obstructive dilatation of the stomach which are amenable to operation Whether etiologically these are all truly non obstructive is a point which we need not now consider For the most part these cases respond more or less readily to systematic and regular lavage careful dieting and general medical treatment, but in some instances the dilatation refuses to subside, and in these it is quite admissible to attempt to remedy the condition by surgical means Various methods have been devised since BIRCHER in 1890 performed the first operation but they are all based on the same principle The ingenious expedient is employed of diminishing the capacity of the dilated stomach by making tucks of one kind or another in its wall. The operation is comparatively easy and attended with but little risk, for of the 28 cases in which according to Professor MAYO ROBSON'S statistics it has up to the present time been performed, in only two has a fatal result occurred, a mortality of a little over 7 per cent. It is hardly necessary to say that gastroplication, as the operation is named, is quite unsuited for any case in which the pylorus is constricted.

Surgical treatment is especially of value in those somewhat rare cases in which tetany and tetanoid spasms are associated with obstructive dilatation of the stomach. These spasms are probably the result of the absorption of a toxin from the dilated organ. In these cases the prognosis is very grave, three patients dying out of every four. The treatment which gives the best results is by a pyloroplasty or by a gastro-enterostomy to do away with the pyloric obstruction.

For injuries of the stomach a laparotomy is urgently required and it gives results as satisfactory as those following injuries of the intestine, though a certain number of recoveries have undoubtedly followed non-operative treatment, as in the case of ALEXIS ST. MARTIN, so highly appreciated by physiologists.

In malignant disease of the stomach the prognosis of surgical treatment is necessarily not so good as in the non-malignant affections, but in many of these cases, absolutely resistant as they are to medical treatment, much may be done. Pylorectomy and partial resection of the stomach are by no means dangerous operations in skilled hands. KOCHER has resected the pylorus in 57 cases and of these the immediate mortality was under 9 per cent.; in one case a woman was alive and well 10 years after the operation. In partial resection of the stomach the results are almost equally encouraging.

When the malignant growth is more extensive, so that practically the whole organ is involved, a complete or an almost complete gastrectomy is required. These are necessarily very severe operations and the mortality we might expect to be very great. In eight cases the whole stomach has been removed and of this number half the patients died. Of those who survived the operation two lived for many months in comparative comfort. In cases in which not quite the whole of the stomach but at least three-quarters have been removed the results are better, the mortality being under 30 per cent. With an earlier diagnosis and a greater readiness on the part of the patient to consent to operative measures we may look for better results, but operations of such magnitude will always have a relatively high death-rate. Professor MAYO ROBSON'S arguments as to the value of gastric surgery were supported by the recital of a number of cases which had occurred in his own practice; and the graphic descriptions of the improvement occurring in the general condition of many of the patients will go far to advocate the more extended practice of surgical treatment in obscure chronic cases of gastric disorder.

◆

THE House of Commons recently went into Committee of Supply on the Army Estimates[1] when an important debate took place in connexion with the vote of £555,000 for the medical establishments. Several Members took part in it and their speeches elicited some interesting and noteworthy observations on the part of Mr. WYNDHAM, the Under-Secretary of State for War. The medical profession has every reason to be satisfied with the tone and spirit manifested on the occasion and with the eulogistic terms in which the services rendered by the Royal Army Medical Corps and by the civil consulting element during the present campaign were recognised. Dr. FARQUHARSON was able to declare that the Army Medical Service had not been made the subject of a single complaint throughout the war operations in South Africa and that the more they heard of what was going on at the front the more they were filled with admiration for the pluck, devotion, and skill which had been displayed and the hard work which had been successfully carried out by its officers. Dr. FARQUHARSON also very pertinently alluded to the inadequate numerical increase of medical officers which the Government were providing for the large permanent augmentation that was to be made to the strength of the army, and he remarked that as too much reliance could not be placed on the system of having recourse to the employment of civilians in times of war it would be necessary, under the longer and more expensive system of medical education now in force, to further level up the inducements to enter the medical service to those obtainable in civil life. Mr. PRICE said that the medical profession had done honour to itself and to the country during the war, and he added that he had the more pleasure in saying this because he had prognosticated an evil condition of things in connexion with the Army Medical Corps. Many Members spoke in a similarly eulogistic strain, while there were no dissentient voices to the proposition that the Royal Army Medical Corps had done admirable work.

Mr. ARNOLD-FORSTER and other speakers referred to the number of men who, having been medically examined in this country, were sent out to South Africa and, proving to be physically unfit for active service, had to be admitted into hospital instead of taking the field. We are afraid that there exists some ground for these complaints. But the fault does not lie with the Royal Army Medical Corps. This is a serious evil and largely an avoidable one. The presence of such men obviously entails a great deal of useless expense to the State, to say nothing of their being a source of trouble and embarrassment to all concerned. We have previously alluded to this unfortunate despatch of invalids to the seat of war, and believe it to be attributable to the fact that the Army Medical Staff being almost entirely in South Africa the medical examinations had to be undertaken by civil members of the profession who were not only new to the work, but under the circumstances of the case were probably often compelled to perform it in a hasty and perfunctory way. This may afford an explanation; it cannot, however, be urged as a valid excuse for the occurrence.

Mr. WYNDHAM, in the course of his reply summing up the various points raised in the debate, adopted a frank and encouraging tone. He declared that the House could not pay too high a tribute to the fortitude, courage, and efficiency which the medical officers had displayed in the field The medical schools in supplying candidates had fulfilled their part of the bargain, to which the Government was the other party in allocating military rank The result had been, he hoped, satisfactory to them as it had been to the Army; but the Medical Department did not reap the whole results of such a change in the first or second year Touching the point that had been raised that the present numbers of the Royal Army Medical Corps were not adequate to the size of the Army they might expect that the inducements which had been offered would, in the course of the next few years, give them numbers even more satisfactory than those which had been forthcoming recently It would be impossible to keep up at all times an establishment of the Royal Army Medical Corps which would be adequate to a time when we were mobilising the whole of the Army for an expedition He explained the action taken by the Government in the appointment of hospital surgeons as consultants at the seat of war, and paid a handsome tribute, which was well received in the House, to the valuable services which they had rendered. He also dwelt upon the enormous progress that had been made by the Royal Army Medical Corps in the sanitation of camps and sanitary work generally, as evidenced by the fact that the percentage of sickness in the present expedition had been the lowest shown in the records of this or any other country We feel that when the present war has come to an end and South Africa has become settled the time will have arrived for harvesting all the results of our experience and subjecting them to very deliberate consideration, sifting, and analysis The ultimate outcome will probably be some broad and comprehensive scheme for the welding and unification of all our military forces into a national army in which the reorganisation of all the medical branches of the service must occupy a prominent place The war in South Africa has proved one thing, if it has proved nothing else—the enormous importance of having a really efficient medical service in time of war

---

[1] THE LANCET, March 24th, p. 894

◆

IN THE LANCET of March 17th (p 785), in commenting on the work accomplished by the Medical Defence Union during 1899, we took the opportunity of making some remarks on medical defence in general and on the importance of organisations of this character to every member of the medical profession The report issued by the London and Counties Medical Protection Society further shows the advantages which are enjoyed by practitioners who happen to be members of such a society when unfounded charges of negligent or unskilful treatment are brought against them or when their professional position is assailed by slanderous reports It is needless for us to repeat the observations on the principles of medical defence which we have made in recent articles, but the report of the council of the London and Counties Medical Protection Society draws attention to another branch of work which occupies a large amount of the time and energy ungrudgingly given by the members of the council of that society in pursuance of their duties—namely, the attempts which they have made to assist in suppressing illegal practice The council reported to the General Medical Council several cases of alleged "infamous conduct" on the part of professional men Before reporting such cases the council made most careful inquiry into the justice and validity of the complaints which had been submitted to them Of the cases thus reported some did not go beyond the Penal Cases Committee, although supported by sworn statutory declarations which appeared to prove conduct usually deemed "infamous" in a professional respect, not merely by medical men generally but by the General Medical Council itself. The grounds on which these cases were refused a hearing by the General Medical Council were not explained to the council of the Medical Protection Society and the members of the latter body naturally are aggrieved at such an omission We can certainly sympathise with the feeling which prompted the following passage in the report now under consideration "And your council feel bound to further express their opinion that the existing arrangements of the General Medical Council do not deal adequately with matters of this sort which affect not only the interests of the medical profession but also those of the public at large" The penal powers possessed by the General Medical Council undoubtedly exercise a wholesome influence in maintaining the honour of the medical profession The Penal Cases Committee probably had good reasons for not prosecuting in the cases above referred to, but we should have thought that those reasons might have been explained to the council of a society one of whose functions it is to bring to the notice of the General Medical Council cases which have already been carefully investigated The proceedings of the Penal Cases Committee are of course, strictly confidential and should be carefully guarded, but so also are the meetings of the council of the London and Counties Medical Protection Society This society and others founded for similar purposes are doing excellent work, and it is to be regretted that their efforts on behalf of the profession should be met by the General Medical Council in a half hearted manner To comment on other matters dealt with in this report would be to repeat much that we have previously said on matters concerning medical defence. But we notice the significant fact, to which we have before alluded, that, as a rule, when a member is annoyed by slanderous reports a simple communication from the society to the offenders has been sufficient to exact an ample apology and to terminate the matter in a manner satisfactory to the member concerned

Annotations.

"Ne quid nimis."

COUNTY MEDICAL OFFICERS OF HEALTH

THE education of local authorities by means of affording them the option of exercising or not exercising certain powers is, as far at any rate as public health legislation is concerned, a somewhat tedious process, and, if we may take the Notification Act as a fair example, we learn that after over a decade of option the country is ripe for compulsion The Local Government Act of 1888 placed within the power of county councils the right of electing a medical officer of health, who should devote his whole time to the duties of his office, and it was doubtless thought by the promoters of the Bill that local authorities of the dignity of county councils would speedily avail themselves of their powers in this respect and appoint highly-qualified and experienced medical officers of health as their advisers. But it has to be admitted that the county councils, in what may be termed their public health aspects, have not realised the great expectations entertained as to them. Truly, there are certain counties which have set good examples—such, for instance, as the West Riding of Yorkshire, Lancashire, Essex, Cheshire, Worcestershire, Surrey, Derbyshire, Staffordshire, and Glamorganshire; but with a few additional exceptions the remaining counties which have, in a sense, taken advantage of their powers have done so in an apologetic, economical, and unsatisfactory fashion. In some cases their action assumes the shape of paying a medical officer of health an honorarium for collecting the reports of the local medical officers of health; in others a sort of retaining fee is paid, while any advice or action is paid for separately; and in others, again, the honorarium is intended to cover apparently all the advice which the medical officer of health is capable of giving. As an excellent example of this latter type we may take the East Sussex County Council, which is now advertising for no less a personage than a *consulting* medical officer. The duties of this office are to be multifarious. He is to prepare a digest of, and tabulate, the local medical officers' reports, to attend the meetings of the sanitary committee and any sub-committee thereof, and to advise and report to them on all matters relating to the exercise of the duties and powers of the county council and its sanitary committee under the several Acts through which county councils now obtain their sanitary powers. For all this work and all this expert advice the fortunate gentleman who is selected is to receive an honorarium of 100 guineas and travelling expenses and the appointment is to extend over a period of *one* year. But we must give the sanitary committee of the county council the credit which is due to them. This committee had passed by a large majority a proposal to elect, what we prefer to term, a statutory medical officer of health—i.e., one who in the terms of the Act "shall not hold any other appointment or engage in private practice without express written consent of the council," and the committee proposed a salary of £700 per annum. Clearly the sanitary committee saw the necessities of the situation and it is to be much regretted that the county council did not endorse their recommendation. County councils in their public health aspects are still on their trial, and it is not by appointments such as East Sussex now proposes to make that the confidence of local authorities will be won. A county medical officer of health should be thoroughly intimate, not only with his district, but also, as far as possible, with the local authorities within its limits. Only by a sound knowledge of the circumstances of each district council can he hope to advise the county council properly or to carry due weight in the county. The local medical officers of health will not improbably resent this sort of appointment, especially if, as is not unlikely, an inexperienced officer is appointed. If appointments of this nature are permitted questions will arise as to whether an amending Act should not be introduced into Parliament to render proper appointments compulsory.

THE UNIVERSITY OF LONDON ACT, 1898.

IN addition to the statutes made for the University of London by the Commissioners, of which we recently gave a summary in THE LANCET,[1] a copy of regulations has now been presented to the Houses of Parliament and ordered to be printed. These regulations define the boards of studies, 32 in number, the names of the teachers of the University who shall be recognised at the various teaching institutions, and the members of the respective faculties. The teachers at the London medical schools in anatomy, physiology, chemistry, biology, and physics are only provisionally recognised until such time as the Senate may make arrangements to secure common courses of instruction for internal medical students in such subjects at one or more centres. These lists are sure to attract much attention from the numerous teachers in the educational institutions included under the Act. A separate series of regulations is also included, setting out the terms under which a student of the University may obtain the degree of Bachelor of Science as the results of any research which he submits to the Senate. Such students, if successful, will be placed in a separate division, and will be adjudicated on apparently by the appropriate board or boards of studies dealing with the subject.

JUDICIAL WARNINGS.

WITH the recent vituperative attack upon a judge of the High Court in the *Birmingham Daily Argus* and with the subsequent proceedings against those responsible for it we should be little concerned but for the fact that Mr. Justice Darling, both on the occasion referred to by the *Argus* and on another occasion during the same assize, made reference to the part which may be played by an unscrupulous section of the press with reference to quackery of a particular class. We have already alluded to the case of Wells,[1] with regard to which his lordship cautioned the press not to make too full reports of the proceedings under any mistaken impression that indecent matter published in the form of a report of legal proceedings was entitled to any special privilege. Wells was awarded 12 months' imprisonment in respect of pamphlets and lectures treating of questions of sex and sexual intercourse, and it is always possible that such matter may be reproduced and the excuse made that it is of public interest and the subject of controversy. The other case at Birmingham to which we have referred was a civil trial for breach of promise of marriage in the course of which it was proved that the plaintiff had been seduced by the defendant and on becoming pregnant had been made ill by mixtures which he had caused her to purchase and to take with a view to procure abortion. These mixtures the defendant had been tempted to purchase by advertisements in the local newspapers, one of which, apparently produced in court, he showed to the plaintiff when he urged her to make use of the concoction offered for sale. A bottle of this stuff was shown to his lordship, who called attention to the similarity of the inscription on the bottle to one of the documents in the Frain case which he tried at the Old Bailey. It was one of those specious notices to which we called attention long before the Frain trial to the effect that the mixture, though harmless, must not be taken for any illegal purpose. Mr. Justice Darling further called the attention of the police to his intimation at the Old Bailey that newspapers publishing quacks' advertisements of abortifacients are liable to prosecution and ought to be prosecuted. In both of these recent instances and in his warning uttered at the conclusion of the Frain trial his lordship may have gone beyond the strict scope of the case immediately before him, but we fail to see that he thereby exceeded his duty as a judge of assize. Some newspapers pander to the tastes of their readers by publishing details of trials that can only appeal to the prurient without serving any useful object. Mr. Justice Darling warned these in order that they might not thereafter say that they had erred unwittingly. A still greater number have published, and many still publish, the advertisements of persons who either in fact sell, or fraudulently pretend to sell, dangerous drugs for illegal purposes, while the police make no effort to stamp out the advertisements and the trade which they enable to exist Mr Justice Darling uttered both his recent warnings in Birmingham, the town in which T Ottey, one of the worst of the advertisers to whom we drew attention in our series of articles on the subject, has long traded, while newspapers in the Midlands and elsewhere have circulated his advertisements In these circumstances Mr Justice Darling's utterances appear to us to be neither uncalled-for nor ill timed They had no reference to respectable newspapers, and there was no need for any respectable newspaper to apply them to itself or to feel aggrieved, either in the case dealt with by the *Argus* article or in that of the advertisements of cures for "obstructions"

[1] THE LANCET, March 24th, 1900, p 859.

A TRIBUTE TO SIR MICHAEL FOSTER

SIR MICHAEL FOSTER'S election to the great council of the nation has been made the occasion of a graceful tribute being paid to him by some of his old Cambridge pupils It was in its inception purely of a private nature and took the form of a letter signed by, amongst others, Francis Darwin, W H Gaskell, L E Shore, H Marshall Ward, A C Haddon, and Walter Heape, and expressed "the loyalty, respect, and cordial friendship' of the signatories They say that they can ill afford to lose either the weight of Sir Michael Foster's name or his guidance at their councils *and they can hardly imagine a greater misfortune than the* breaking of the bond between him and themselves "But, they continue, "we rejoice that an arrangement has been arrived at which will allow your interests still to centre in Cambridge, giving you at the same time the opportunity of working in a wider field, where you may do for England what you have already done for Cambridge and where your services to learning may benefit not only England but the whole English speaking race' Sir Michael Foster has won fame and honours in foreign countries as well as in his own land, but few things, we imagine, will have pleased him more than this simple and spontaneous proof of the esteem and affection in which he is held by those whom he has trained The work of a teacher is always hard and ofttimes disappointing, but there can be no greater pleasure to a teacher than to know that his efforts are appreciated and bring forth such fruit as he would desire

GUARDIANS AND VACCINATION

WHEN last year the Leicester guardians refused to carry out the law by appointing a vaccination officer there were other districts in the Midlands containing a large number of consistent opponents of vaccination which had, like Leicester, returned guardians to office practically pledged to withstand and render nugatory the Vaccination Act In more than one of these cases as well as in that of Leicester legal proceedings were commenced by the Local Government Board with a view to compel the appointment of a vaccination officer, and in the districts where this happened the proceedings against the Leicester guardians, which culminated in their committal for contempt of court and ultimate surrender, were naturally watched with interest In such circumstances as these it was borne in upon the guardians of Wellingborough, among others, that to disregard the order of the court was, as we expressed it at the time, as ineffectual a manner of resisting the operation of an Act of Parliament as to try to stop a steam roller by sitting down before it and making faces Accordingly when the Leicester guardians acknowledged defeat the Wellingborough guardians ceased to court it, complying with the law without further compulsion being exercised upon them In preparing for resistance, however, they had apparently incurred law expenses to the extent of £43 10*s*, and this sum they put down in their account to be paid out of the funds of their district, should it be passed by the auditor to whom the accounts had to be in due course submitted This gentleman very properly refused to do anything but surcharge it to the persons responsible for its expenditure, holding an adjourned audit to allow them to protest should they choose to do so A Mr Abbott appears to have said at the adjourned audit that at the request of his constituents he had given a pledge to do all he could to make the Act a dead letter and to prevent prosecutions for non compliance with it A number of Mr Abbott's colleagues were equally candid in the avowal of their intentions and motives, and the auditor can hardly have felt any hesitation as to the course which it was his *duty to adopt He accordingly surcharged those who* were present when the cheque for the amount under discussion was signed and who had taken part in the affair throughout It will be observed that no pretence was made to assert any obscurity of the law or to claim that the legal expenses had been incurred in order to assert or defend any right genuinely believed to exist, and it may be pointed out that although the auditor disallowed the charge in his own discretion had he failed to do so any ratepayer might have appeared and objected to it *Presumably* other auditors have done the same in similar cases, should they not have done so it is to be hoped that ratepayers will call attention to the burden of fruitless litigation improperly cast upon the rates

"IS INSANITY INCREASING?"

A PAPER was read at the Manchester Statistical Society on March 14th by Dr J M Rhodes, who was for some years the chairman of the Chorlton Board of Guardians and is now the chairman of the Chorlton and Manchester Joint Asylums Committee, with the title, "Is insanity increasing?' Dr Rhodes pointed out that according to the fifty third annual report of the Commissioners in Lunacy the total number of lunatics in England and Wales on Jan 1st, 1899, was 105 086, being an increase in a year of 3114, "the largest annual increase yet recorded' But we are not alone "In France the last decennial return shows that the ratio of certified insane has increased from 247 to 252' and the ratio of persons admitted with *folie alcoholique* has increased in the 10 years by fully 100 per cent Germany also gives the large increase of 6000 in 10 years Denmark has a much lower ratio than other European countries, but it has risen from 137 3 to 165 7 per 100 000 during the same period, the greatest increase being in Copenhagen where the cases are one in 300 against one in 400 for the rest of the country The increase in Belgium is large and steady, and the statistics are remarkable as showing the great preponderance of *unmarried cases 7600 of the total* being single and only 2300 married or widowed In England the married or widowed exceed the single, the numbers being 10 272 married to 7744 single Italy also shows an increase of 24 per cent in four years, and as in Belgium the unmarried exceed the married insane, in the former nearly in the proportion of two to one In the United States during the two decades from 1860 to 1880 the insane increased in number by nearly 400 per cent but the rate of increase in the last decade was not so great From the varying legal enactments dealing with the treatment of lunacy in different countries, however, it is difficult to make safe comparisons From statistics given by Dr Rhodes it would appear that some insanity is part of the price of civilisation, and it seems also that the standard of the civilisation of a country can be gauged by the provision it makes for the insane

In countries where education is low little is done for this class as compared with those where it is high. Until our own time only the violent and dangerous cases were found in the asylums, while now more than 50 per cent. are patients suffering from harmless dementia and melancholia. This fact accounts for a large increase in the number now cared for in our asylums. In Lancashire the accommodation is utterly inadequate to meet the demand, and the same holds good all over the country. Dr. Rhodes considers that "we need a thorough inquiry into the lunacy laws and their administration, and that better provision is urgently needed for the middle classes." In many cases the clerk, the warehouseman, or the skilled workman would be very glad to pay something for a relative as a private patient, but the county asylums are so full that they have only room for pauper patients, so that they must go as paupers or not at all as the charges elsewhere are beyond their means. There is great need for classification, and Dr. Rhodes thinks that some of the existing defects might be met by the "colony" plan of building asylums. The increase in Lancashire is confined to three classes—"working in handicrafts," "domestic," and "miscellaneous"—and the last class alone accounts for an increase of 2138 cases. Dr. Rhodes also thinks the increase is not nearly so great as the figures would indicate. "Public opinion in regard to insanity has changed. The insane are looked upon as requiring humane and scientific treatment by methods which can be better carried out in asylums than in the homes of the patients." During the discussion that followed the paper the chairman of the Manchester Board of Guardians pointed out that the number of the inmates of the asylums was kept up by the prolongation of life from the care and attention which they received. Some of the patients were 80 or 90 years of age.

THE WEST AFRICAN FRONTIER FORCE.

THE general medical history of this force until March 31st, 1899, is given in a report just issued by the Colonial Office. Dr. Wordsworth Poole, the principal medical officer, states that the first detachment of the force landed in Africa in September, 1897, and by the end of March, 1898, new arrivals had made up the two battalions to their full complement. The majority of the places where the force was stationed were on the banks of the river Niger. The medical staff consisted of eight medical officers (civilians), three nursing sisters (civilians), and 14 non-commissioned officers of the Royal Army Medical Corps. From April 1st, 1898, to March 31st, 1899, the average strength of the force was 156, of whom 27 died in Africa and 55 were invalided to England. Of the 55 thus invalided five died either on the passage or very soon after arrival in England. So that 32 deaths may be ascribed to the effects of service, being a death-rate of 20 5 per cent. per annum. The causes of the 27 deaths in Africa were as follows: malarial fever, 12; blackwater fever, 6; abscess of liver, 3; dysentery, 2; killed in action, 2; drowning, 1; and sunstroke, 1. The causes of invaliding to England were as follows: blackwater fever, 20; debility, 14; malaria, 6; dysentery and syphilis, 5 each; epididymitis, abscess of liver, hæmoptysis, rheumatism, and beri-beri, 1 each. The total number of admissions to hospital in Africa for all diseases was 950, which with an average strength of 156 gives an average of six admissions to hospital for each man during the 12 months. A few of these admissions were as follows: malarial fever, 734; blackwater fever, 36; diarrhœa, 37; dysentery, 19; and sunstroke, 4. An extensive trial was made of the use of quinine as a preventive of malaria. More than half the number of Europeans took five grains of quinine every day during the whole period they were in the country. Others took a dose of 15 grains *once a week*. A few *took no* quinine. Careful records were kept for a period of six months of the amount of fever occurring in the members of these three classes. The results, however, of the experiment did not afford the basis of a conclusive opinion.

THE EASTER HOLIDAYS EXTENSION.

A MOVEMENT now on foot for the extension of the Easter holiday is certain to obtain a large amount of public sympathy. The position of the Saturday before Easter is in the case of very many persons nothing less than a grievance. But for it an unbroken period of four days would be available for that change to country air and recreation which every dweller in a great city has found reason to value highly. Unfortunately the total cessation of business for even so short a time is prohibited in some trades by the daily needs of our existence. It is quite otherwise with the work which is carried on in most of the larger warehouses and shops which are not engaged in the provision trades. An increasing number of these latter, we are pleased to find, are disposed to concede the whole of Saturday to their employés. They may well do this, for the amount of business done on this day—or, as it should be better styled, half day—is not great. On the other hand the gain in point of health both to employers and employed which the cessation of work between Thursday and Tuesday implies is considerable.

HEAT-STROKE AND SUN-STROKE.

IN an article which occupies considerably more than half of the *Archives de Médecine Navale* for January Dr. Moussoir, a French naval surgeon of the first class, claims to be the first observer to have established a fundamental distinction between heat-stroke and sun-stroke, and contends further that a correct appreciation of his discovery would result in a large saving of human life. "I bring here," he says in his opening sentence, "the solution of a problem which has never been resolved in a satisfactory manner"; and a little lower down he expresses his conviction that "the originality of the etiological theory, the prophylaxis arising therefrom, and the proposed pharmaceutical treatment justify the publication" of views that would have seen the light three years sooner but that he was compelled by the exigencies of service to spend the greater part of his time in transferring his household gods from one station to another, including Tonkin and Bac-Ninh. Heat-stroke, according to Dr. Moussoir, is a pathological condition produced by the action on the whole surface of the body during a sufficiently prolonged period of a temperature exceeding 104° F., whereas sun-stroke is a pathological condition produced by the action on the cranium during a period, which need not necessarily be long, of sufficiently intense solar radiation. The high temperature which gives rise to heat-stroke may be either moist or dry and may emanate from any source. *Moist heat, as in a* stoke-hole on board ship, brings on heat-stroke by preventing the evaporation of perspiration, while a dry heat, by shrivelling up the skin into a parchment-like substance, prevents the exudation of perspiration, and most probably also produces an analogous condition in the pulmonary alveolar tissue. Heat-stroke causes its ill effects through the superheated blood, which reacts on the nervous centres. It comes on gradually, but may simulate suddenness when the will power by which the subject was sustained is abruptly withdrawn. Stokers are able to endure a damp hot atmosphere in narrow, ill-ventilated spaces because they work naked or nearly so, whereas soldiers on duty in the open air succumb to heat-stroke because the *caloric increases* beneath their thick clothing, which also hinders the *evaporation* of sweat. To prove this three thermometers should be placed—*the first in the shade, the second in the sun*, and the third likewise in the sun but wrapped in a piece of cloth. An experiment frequently repeated by Dr. Moussoir gave results as follows: first thermometer, 82 4°; second, 110 3°; and third, 127 4°. Sun-stroke, or insolation, is not induced by high temperature but by the intense radiation which the sun alone, owing to its enormous volume (1,200,000 times that of the earth), can supply, the chemical rays, the vibrations of which are more rapid and therefore more penetrating than those of their calorific and luminous congeners, being the exciting cause. Fonssagrives and Corre imagined that the sun-stroke of low temperature during clear weather was due to the action of *light on the retina*, but *this* must be an error because, owing to the incautious exposure which is then likely to take place, the affection is very frequently met with while the sky is overcast. The chemical rays emitted by the sun can pierce through white clouds freely, but are almost entirely arrested by black substances and partially so by red. These facts explain the immunity from sun-stroke of negroes and people with swarthy complexions and the diminished liability to it of the ruddy. To produce sun-stroke the rays must impinge upon some part of the brain-case, the effect being transmitted thence to the as yet unlocated heat centre by reflex action. The process precisely resembles what goes on when a perspiring scalp is exposed to a draught and sneezing coryza and other reflex phenomena quickly ensue. Covering the head preserves from sun-stroke, but just as is the case with thick clothing a helmet can only assist in the development of heat-stroke. The mean of a series of observations with suspended thermometers showed that the temperature inside a regulation helmet was 10° C. higher than in the shade of a verandah. In heat-stroke the disease begins by heating the blood, but in sun-stroke this condition of the circulating fluid is secondary; the fact, however, that in both affections the blood becomes superheated serves to explain the resemblance of the symptoms. Sun-stroke or insolation can only occur within the tropics because in that region alone the sun's chemical rays are sufficiently intense to produce the necessary reaction. In support of this statement Dr. Moussoir appends a number of ingenious diagrams dealing with the refraction of solar rays, but these aids to comprehension require to be seen while the accompanying lucid letterpress should be read *in extenso*. So far Dr. Moussoir may, perhaps, be held to have supplied a *primâ facie* case in support of his somewhat ambitious exordium, but with regard to treatment his promises can scarcely be looked upon as fulfilled. Excitation and antipyrin are insisted upon, together with ice, cold affusion, and the rest of the stock remedies as usually recommended. Quinine, however, is discarded utterly, the writer having no belief in its antithermic properties, seeing that in small-pox, scarlet fever, &c., its exhibition fails to reduce the temperature. In paludal fevers the alkaloid acts as a parasiticide, and in sun-stroke there are happily no microbes. Incidentally painting with guaiacol is mentioned, but the effects are said to be prohibitively uncertain. Under its influence hyperthermia is apt to degenerate into hypothermia with cardiac collapse. Among the predisposing causes of heat apoplexy Dr. Moussoir mentions the horizontal position, contending that the heat rays, both direct and refracted from the ground, have thus a much larger surface to act on. This would seem to supply an argument against the Indian practice of taking a siesta during the heat of the day.

ROYAL METEOROLOGICAL SOCIETY: A JUBILEE CELEBRATION.

THE Royal Meteorological Society will attain its jubilee on Tuesday next, April 3rd, having been founded on April 3rd, 1850, and arrangements have been made for keeping the anniversary with due observation. At a commemoration meeting to be held in the Institution of Civil Engineers, Great George-street, Westminster, at 3.30 P.M., the President, Dr. C. Theodore Williams, will deliver an address, and the *delegates from other societies will be received.* A conversazione will follow at the Royal Institute of Painters in Water Colours, Piccadilly, at 8.30 P.M. In addition to the pictures in the galleries there will also be an exhibition of meteorological instruments, models, and photographs, and lantern demonstrations will be given by Colonel H. M. Saunders, Mr. T. C. Porter of Eton, and Mr. W. Marriott. On the following day (Wednesday) there will be, by permission of the Astronomer Royal, an excursion to the Royal Observatory, Greenwich, and the commemoration meeting will close with a dinner at the Westminster Hotel at 7 P.M. As a memento of the jubilee of the society a bronze commemoration medal, bearing on the obverse a portrait of Mr. Luke Howard, F R S, has been struck.

THE MIDWIVES BILL: A MEETING OF PROTEST.

A MEETING of medical and lay constituents of the boroughs and divisions of South-East London and adjacent parts of Kent and Surrey to consider and adopt measures to resist the registration of midwives, and particularly the Bill now before Parliament, will be held at the Cannon-street Hotel, E C., on Wednesday, April 4th, at 4 o'clock P M., when the chair will be taken by Mr. George Brown. The following Members of Parliament for the boroughs and divisions comprised will be invited to meet the Direct Representatives of the profession on the General Medical Council:—Right Hon. C. T. Ritchie (Croydon), Lord Hugh Cecil (Greenwich), Sir J. Blundell Maple, Bart. (Dulwich), Colonel Edwin Hughes (Woolwich), Colonel P. H. Dalbiac (Camberwell, North), Captain Cecil Norton (Newington, West), Mr. A. H. A. Morton (Deptford), Mr. John Penn (Lewisham), Mr. H. W Forster (Kent County, West), Mr. C E. Tritton (Norwood), Mr. H. C. Leigh Bennett (Chertsey), Mr. James Bailey (Walworth), Mr. F. G. Banbury (Peckham), Mr R K. Causton (Southwark, West), Mr. J. C. Macdona (Rotherhithe), Mr. A. Lafone (Bermondsey), and Mr. F L. Cook (Kennington).

UNUSUAL CASES OF INSOMNIA.

PROFESSOR H. OPPENHEIM of Berlin has contributed to the *Berliner Klinische Wochenschrift* (No. 49, 1899) a valuable clinical lecture devoted to some unusual cases of insomnia. Various types of insomnia exist requiring different methods of treatment Thus, to the psychical or ideogenic type belong all cases in which mental worry and overstrain, violent emotions, morbid concepts, hallucinations and delusions, or other pathological mental states are the causes which prevent sleep. The insomnia of many lunatics and of patients suffering from grave hysteria and neurasthenia belongs to this category. Some patients suffer from interruptions of sleep owing to the appearance of certain "phobias" or terrifying and startling ideas which may occur while falling into sleep Closely related to the psychical is that type in which a hyperæsthesia of the senses (hearing, tactile and cutaneous senses) interferes with sleep or renders it difficult. The second category includes types of insomnia due to pain (algogenic type). Apart from bodily pains of various sorts there may be disagreeable or irritating sensory disturbances which serve to promote insomnia—e g, pruritus, thermoparæsthesia, excessive flushings and feelings of heat, and tinnitus aurium. Gastro-intestinal disturbances (colic and enteritis) play an important part and cardiac and respiratory disturbances also act prejudicially in driving away sleep. There is also an insomnia of sexual origin arising from various conditions which may disturb or unduly stimulate the sexual life. At times sleep itself is a cause of troubles which interrupt and break it, thus dreams, night-terrors, and nightmares arise in the course of sleep, and when they have attained a sufficient intensity they produce wakefulness. Professor Oppenheim mentions two interesting cases, in one of which the patient, who was perfectly well in the waking state, was frequently awakened from sleep by the pain and discomfort of severe girdle-pains, while the other patient was subject to attacks of occipital neuralgia only during sleep. There are pains and disagreeable experiences which are intimately connected with sleep just as there are forms of epilepsy which only manifest themselves during sleep (nocturnal epilepsy). A case is also reported of a woman who had recovered from influenza with the following extraordinary result. As long as she was awake the heart's action and the respirations were normal, but as soon as she went to sleep they subsided to so slow and feeble a rate as practically to cease and she was in danger of dying. This state of affairs was so alarming that she had to be constantly watched and kept by artificial means from falling into sleep until by the administration of drugs (bromides and nerve tonics) the condition eventually passed away. Another case is recorded of a married woman, aged 35 years, who one day unexpectedly received bad news. She became excited and agitated by this and her sleep was disturbed by attacks of dyspnœa which came on at intervals of from 15 to 30 minutes all through the night. During these attacks she would start up unconsciously and on more than one occasion she sustained injuries by so doing. She was free from symptoms of hysteria. In about a minute after being thus awakened she would become conscious and would be able to answer questions and she could then go to sleep till interrupted again as before. Bromides were administered to this patient and she eventually recovered. The great importance of treating or averting insomnia and thereby of obviating threatened mental breakdown is urged by Professor Oppenheim as chiefly needed in all cases with hereditary tendencies to mental disease.

OBSERVATIONS ON TUBERCULOUS CATTLE IN CANADA.

A report which has recently been issued by the Canadian Government embodies the details of a number of experiments which have been carried out by Dr. J. G. Adami of the McGill University and Dr. C. F. Martin on cattle recognised to be tuberculous by the tuberculin test. In November, 1897, 10 cows were received at the Government farm at Outremont from Ottawa. They had been tested with tuberculin and had all reacted, although only one displayed any clinical evidences by which the chief veterinary inspector (Professor McEachran) could suspect the disease. The 10 cows were placed each in a separate stall in a byre newly built for the purpose, the best attention possible being given to hygienic and dietetic arrangements. The partitions were of such a height (five feet) that there could be no contact between the animals, and each cow was allowed its own special exercising ground where it could not be approached by the others. In December seven of the subjects were re-tested but only two gave definite reactions. A month later (Jan. 15th, 1898) the whole 10 were again tested and three reacted; two of those which had reacted in December showed no rise of temperature now and the only reacting one of the previous seven was the cow which had exhibited clinical evidences of disease. The cows were not inoculated again until the end of April and the experiment was made with two of them to see whether repeated reactions could be obtained by giving increasingly large doses, as is known to be the case in the human subject. On April 28th double the usual dose was injected without effect; on May 2nd four times the proper amount was given without result. It would thus seem that in this respect tuberculin acts somewhat differently in cattle to the way in which it acts in human beings. Dr. Adami and Dr. Martin consider that very possibly these large injections had some curative effect as these two cows at death showed but a trace of tuberculosis. They draw attention to the opportunity which is presented by the knowledge of no reaction following if the animal has been recently tested for a vendor to get rid of a tuberculous animal as a sound one. This fact is well known to veterinarians in England, and it is customary to allow at least three weeks or a month to elapse before re-applying the test. Probably the most important fact of interest to the medical practitioner was ascertained by the examination of the milk for tubercle bacilli; these were clearly demonstrated in the milk of six of the cows, although the udders were apparently healthy both to external appearances and on subsequent post-mortem examination. The milks were examined at frequent intervals, sometimes with positive, sometimes with negative, results. At times the bacilli were present in considerable numbers and at other times there were very few in the field. Guinea-pigs, rabbits, and calves were fed or inoculated with milk from each of the cows, the results being carefully noted. The chief conclusions arrived at by Dr. Adami and Dr. Martin were:—1. Each of the cows which had reacted to tuberculin exhibited upon post-mortem examination seven months later distinct evidences of tuberculosis, although in no instance were the lesions very extensive. In no case did the most searching examination demonstrate tubercle in the mammary gland. 2. The first injection of tuberculin is capable of detecting the slightest degree of infection in cattle, but the injection seriously affects the development of another reaction within an average period of rather more than a month. A second reaction is often not obtained within 30 days, even by giving double, or four times, the dose of tuberculin. 3. It is possible that repeated doses of tuberculin have a certain curative power. 4. Although the udders were free from tuberculous disease the milk of several contained from time to time tubercle bacilli, the latter being demonstrated beyond dispute by the usual methods of staining and by inoculation experiments. 5. The milk of animals suffering from slight grades of tuberculosis possesses only feeble infective powers, although occasionally without obvious cause the number of bacilli present in it might increase greatly, and in one case the number suddenly became so great that the milk at this period must have been dangerous.

MEDICAL APPOINTMENTS IN EGYPT.

The Quarantine Authority of Egypt is about to appoint after public competition one woman doctor to be attached to the department at Suez at a monthly salary of from 22 to 28 Egyptian pounds. Candidates for the post must submit: (1) the original or else a certified copy of their diploma as doctor; (2) a certificate of sound health; and (3) a formal pledge of their willingness to take up the duties of the post in case of their being nominated to it during the course of the month which follows that of the formal nomination. Candidates should also submit the languages which they know. They are also warned that in case they wish to resign the post they can only do so on giving three months' notice to the President of the Sanitary Council. The examination will close on April 30th, 1900. The quarantine authority is also about to appoint after public competition one director of the second class at a monthly salary of from 22 to 28 Egyptian pounds. Candidates must submit: (1) the original or else a certified copy of their diploma as doctor of medicine and surgery; (2) certificates of their having studied bacteriology and epidemiology; (3) a certificate of sound health; and (4) a formal pledge of their willingness to take up the duties of the post in case of their being nominated to it during the course of the month which follows that of the formal nomination. Candidates must also submit their age and the languages which they know. They are also warned that in case they wish to resign the post they can only do so on giving three months' notice to the President of the Sanitary Council. The examination will close on April 30th, 1900. Applications for either of these appointments should be sent to Dr. O. Armand Ruffer, *Alexandria, Egypt.*

STREET NUISANCES.

WE are glad to see that the London County Council is persevering in its efforts to make London less objectionable. At the weekly meeting held on March 27th a recommendation of the General Purposes Committee was agreed to that a conference should be held with the various local authorities to consider the question of street and traffic regulation. All sorts of points are involved in this decision. The question of traffic alone involves the ever-increasing number of omnibuses which in narrow streets, as, for instance, Bond-street, are gradually getting to be a greater nuisance than convenience. Some check, too, should be placed upon the perpetual disturbance of the streets by gas, telephone, electric lighting, water, and hydraulic power companies from one or the other of which the Strand and adjacent streets have never been free since last July. Something should also be done to stop newspaper hawkers throwing away the innumerable posters which they carry—a practice which makes Piccadilly-circus a perfect rubbish shoot. "Mud Salad Market," as *Punch* long ago called the market owned by the Duke of Bedford, is, we suppose, a necessary evil, but all the same it is out of place in the midst of a great city.

THE MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

THE first annual general meeting of this institution was held on Wednesday last, March 28th, when Dr. O Theodore Williams urged the members to put their shoulders to the wheel as Mr. Hutchinson had done and help to tide the college over a critical position. Dr. Williams, who is treasurer of the College, put the whole difficulty quite tersely when he said that they could not carry on the work with an income of £800 and an expenditure of £2000 a year. In the course of his remarks one of the audience said the State ought to help, to which Dr. Williams replied that from what they knew of the British Government he did not think that they would find any instance in which the Government had so helped, but the members could persuade their friends to give donations. Mr. Hutchinson said that they should remember the Hunterian maxim that organisation depended on life and not life on organisation. The life must come from within, and they all ought to be zealous to work to a grand success. At first they could not be wholly self-supporting and must appeal to the members at large to do what they could. The pecuniary liabilities of the College should not be entirely thrown on the medical profession. The paucity of general practitioners on the Council led Dr. Snape to say that as the members of the College were general practitioners and formed the audiences at the lectures and the students at the classes their support was essential to success, and adequate representation should be accorded to them on the council. Dr. Fletcher Little considered that if the College was to be a practitioners' College, as he hoped it would be, they must be properly represented on the council. Sir William Broadbent, the chairman of the council of the College, said that proper representation of the general practitioners on the council would be granted when that body was re-elected next year. We hope that the financial position of the College will soon be much improved, but we agree with Dr. Williams that salvation will come from self-help, and that no State assistance can be hoped for. This may be regrettable, but it is a fact.

THE SUPPLY OF MEDICAL STUDENTS.

THE General Medical Council has just issued its Medical Students Register, which is the list of medical students registered during the year 1899. There is an increase of 102 in the number registered in the United Kingdom in 1899 as compared with the number registered in the previous year, being 1711 and 1609 respectively. But taking the last two quinquennial periods into the estimate we find that the later, ending in 1899, gives 8441 registrations of medical students and the former 9340. In other words there are 899 fewer registrations in the later quinquennial period than in the former, or an annual average of about 177 less per year. The register contains much interesting information as to the schools and the date of commencement of medical education of the students registered, the division of the kingdom in which the registration takes place, the regulations of the General Medical Council for the examination and registration of medical students and other matters.

THE THREATENED EXCLUSION OF FOREIGN MEDICAL PRACTITIONERS FROM ITALY.

MUCH anxiety exists among foreign practitioners in the kingdom of Italy in respect of legislation said to be contemplated by the Italian Government to prevent all foreign medical men from practising in Italy unless they hold an Italian qualification or the country from which they come grants a reciprocal right to duly qualified Italian practitioners. We showed last week from an examination of the minutes of the Executive Committee of the General Medical Council that it is informed on this subject. But it is one calling for the serious attention of the Council in May. We cannot imagine that the friendly Italian Government will allow itself to act hastily in a matter so deeply affecting not only British medical men but also the British invalids who flock to Italy in thousands every winter. At the very least, they will surely not include in such legislation British practitioners already established in Italy. On our side there must be more decision and promptness or we shall provoke legislation that will be unfortunate and narrow. We must not forget that Italy is only proposing to do very much what we do already—with this difference, that Italians may practise here without any probability of objection on the part of the law or of the General Medical Council.

THOMSEN'S DISEASE (MYOTONIA CONGENITA) IN A BROTHER AND SISTER.

DR. J. S RISIEN RUSSELL demonstrated at a meeting of the Neurological Society of London on March 15th two cases illustrating the heredity of Thomsen's disease, the patients being a Hebrew boy and girl. The children were apparently of natural development, not backward in speech or walking, and free from fits of any description. The boy, aged 15½ years, seemed somewhat poorly developed for his age. His growth appeared to have been natural until he was five years old, when a difficulty in performing voluntary muscular movements began to be noticed. His condition gradually grew worse. It was most marked in the morning and on attempting to get up or to walk the movements of the arms and legs were hampered by stiffness of the muscles. Gradually in the course of the day this stiffness diminished. Walking was always difficult, however, especially after a period of rest. On closing the eyelids tightly the patient could not readily open them again and after closing the hand tightly the extension of the fingers was slow and difficult. The knee-jerks were normal and there was no spasticity. The girl was aged five and a half years and presented similar phenomena but in a less marked degree than did her brother. Her trouble seems to have commenced at the age of four years, and at the date of the demonstration (16 months after) it was more noticeable. In the four months during which she had been under observation the condition had grown worse.

THE PROGRESS OF THE MIDWIVES BILL.

THE Midwives Bill, having passed through the Standing Committee of the House of Commons on Law, now awaits the report stage. Throughout the proceedings of the Standing Committee the promoters of the Bill had affairs their own way despite the vigorous resistance offered by Mr. T. P. O'Connor and Mr. Lloyd George; while, as will be seen from our Parliamentary representative's account, the supporters of legislation evidenced their interest in the measure with as much clearness as the opponents displayed their apathy. In spite of the favourable position which the Bill now enjoys some modifications may be expected in response to the representations of the General Medical Council. The General Medical Council has strongly urged the inclusion of a clause not yet in the Bill requiring that in obstetric cases presenting "symptoms of difficulty, abnormality, danger, or disease on the part of the mother or of the new-born child" the licensed midwife must apply for qualified medical assistance. An amendment to this effect was brought before the Standing Committee by Colonel Milward, but was lost. The Council will, we are sure, use what pressure it can to ensure the addition of such a provision to the Bill before it becomes law. The Government are stated to consider that inasmuch as the rules of the Midwives Board have to be approved by the General Medical Council, the General Medical Council will have full opportunity after the Bill becomes an Act of restricting the practice of the licensed midwife to the limits of proper obstetric nursing. Under the measure which has just passed through the Standing Committee we believe verily that the licensed midwife can by no means be so restricted—a situation that will commend itself favourably to the limited intellect of Mr. Atherley Jones, Q C.—but certainly the legal provisions making attempt to confine the new order of nurses to nursing should be an integral part of the Bill.

THE RESIGNATION OF SIR WILLIAM T. GAIRDNER.

WE announced last week the intention of Sir William Gairdner to intimate to his class in the University of Glasgow his decision to resign his professorship of the Practice of Physic. He did so on Friday, March 23rd, in eloquent terms of dignity and regret befitting the occasion There was something exceedingly touching in the sentiments of Sir William Gairdner expressing the reluctance with which he took such a step while still feeling the keenest interest in the work of the class-room and the ward. "My class-room and my hospital remain now as they have all along been, the greatest of my occupations and the sources of the most profound satisfaction in endeavouring to serve thereby my day and generation." There is no abatement in the force with which Sir William Gairdner follows the development of medicine. It is on the contrary his deep sense of the rate and scale of this development which determines him to give way to one with "at least a younger pair of eyes and perhaps a younger brain as well." He will scarcely admit any age in the brain that should make him resign, but his eyesight is not equal to the task of the enormous amount of reading necessitated by his professorship and the claims of the new science of bacteriology. Sir William Gairdner's final words of acknowledgment to his "generations of pupils" and "succession of helpers in class and ward duty," will be cherished by men all over the world as well as by those gentlemen—Carslaw, Ness, and Watson—who close the great army of assistants and are fortunate enough to find their names associated with the work of such a master and specified in historical words. This is not the time, happily, to count up what Sir William Gairdner has done for the health of the inhabitants of Glasgow. This event of his resignation has an interest wherever medical science and medical character are prized. His *forte* as a teacher has been that he has always been a learner. He will, we hope, long continue to be both, and the profession at large will be glad to place itself *in statu pupillari* whenever he may choose to announce the results of his judgment and his experience.

OUR Birmingham correspondent, in a note in our issue of Jan. 27th, referring to the Anglo-American Assurance Company, introduced the name of Sir William MacCormac. We have been requested to give publicity to an entire repudiation by Sir William MacCormac of any connexion whatever with this company. We are sure that all our readers must have seen that the name of the President of the Royal College of Surgeons of England was unwarrantably used as a decoy by the convict who was canvassing the profession recently on behalf of this swindle.

THE annual meeting of the Factory Girls' Country Holiday Fund will be held on Friday, April 27th, at 3 o'clock, at the Mansion House, by permission of the Right Hon. the Lord Mayor. The Lord Mayor will take the chair, and among those announced to speak are the Bishop of Rochester, the Bishop of Bristol, Mrs. Scharlieb, M.D. Lond., and the Very Rev. Dr. Adler, Chief Rabbi.

DURING the absence abroad of Sir Savile Crossley Viscount Duncannon will undertake some of the duties of the honorary secretaries of the Prince of Wales's Hospital Fund for London. All communications to the Fund should, as before, be addressed to the honorary secretaries, Prince of Wales's Hospital Fund, Bank of England, London, E.C.

THE second Lees and Raper Memorial Lecture will be delivered by Mr. Victor Horsley in St. James's Hall, Piccadilly, W., on Friday, April 27th. The subject is announced as the Effect of Alcohol upon the Human Brain.

PROFESSOR OSLER has telegraphed from Baltimore asking us to announce that he is not a candidate for the Chair of Medicine in Edinburgh University.

THE WAR IN SOUTH AFRICA.

EVEN apart from the fact that nothing succeeds like success we think that a change of tone and of opinion may be traced in the foreign press in regard to the war in South Africa and the way in which it was brought about and has been conducted. With the arrival of fuller and more precise information as to what was the actual condition of affairs at the time when the war broke out it begins to be recognised in this country also that, speaking generally, our generals in South Africa did the best which they could under the circumstances and were, as a matter of fact, compelled to follow the course of action which they pursued. Unfortunately it was incorrectly assumed by the Government of this country—and the assumption was founded upon the views held by many local authorities in South Africa—that the force under Sir George White would be able to deal with any army which the Boers could bring against it. It was not foreseen, as it might have been, that the Boers would invade Natal in force. Urgent political reasons also came into play, advanced posts were held, and the result was that the military authorities and Sir George White had no option but to occupy Ladysmith where the defending force was shut up for some months. Ladysmith was a big store depôt. It should never have been selected for that purpose, for it was a strategically unsuitable position, and in any case it should have been strengthened by defensive works and a proper armament, which it was not, when it was first fixed upon years ago. But neither Sir George White nor Sir Redvers Buller was responsible for this. They had to take things as they found them and make the best of them, which they undoubtedly did. We are glad to hear, by the way, that Sir George White, although still suffering from fever, is better; he has just left Cape-town for England. The siege of Ladysmith will add another page to our national history illustrative of fortitude, endurance, and bravery, but the glory of it has been purchased at the cost of a vast amount of sickness and suffering and also, we are afraid, at the expense of shattered health in many of the survivors.

There is a comparative lull in the news from the theatre of war at the present time. Taking stock of our losses it appears that up to March 24th the British casualties in South Africa in killed, wounded, missing, and prisoners (exclusive of sick) are returned as 1000 officers and 14,403 non-commissioned officers and men. The sick rate in comparison with that of the killed and wounded has so far been exceptionally low. This no doubt is attributable to many causes, such as the healthy nature of the climate, the forethought, care, and preparation which have been exercised, the ample provision that has been made for the requirements of the campaign, and also to the attention that has been paid to camp hygiene. There does not seem to have been any wholesale contamination of water-courses (if we except the case of Ladysmith where the water was probably fouled and gave rise to much of the enteric fever and dysentery that prevailed there) such as occurred in some of our previous campaigns in South Africa. Still, there has been a good deal of enteric fever and dysentery, and these diseases have not by any means been confined to besieged garrisons. It is the nature of such diseases and of other diseases incidental to field service to spread as the campaign goes on. Happily the forces have been a good deal on the march and consequently have been changing their ground, which is about the best thing that could happen under the circumstances, and the invasion of the Transvaal and the march to Pretoria will take the army over tracks of comparatively virgin country. The chief source of anxiety at the moment is as to the relief of Mafeking, which, despite the pluck and the cheerful tone the little garrison have maintained throughout the siege, must be hard pressed and increasingly so. It is reported that the army medical service with General Buller's force has been more than usually active of late and that arrangements have been made for a considerable augmentation to the strength of the stretcher-bearers and dhoolie-bearers of the force; if so, we may shortly anticipate to hear news of a movement. Should General Buller have to advance along the route which now seems probable he will still be destined to encounter a most difficult line of country and one which is, topographically speaking, most favourable to Boer tactics. Be this as it may, his soldiers evidently have confidence in his generalship, for it is refreshing to read or hear of their testimony to his ability as a general and to his soldierly qualities. If his column has to force passes we may still expect some severe fighting and much occupation for its medical staff and sick transport. Lord Roberts and Lord Kitchener are presumably actively engaged in securing a safe base and lines of communication and in making their final arrangements for the march towards Pretoria. The war is not by any means over yet, but the course will, at any rate, soon be clear for attempting, and as we trust successfully, the carrying out of the definite strategical plans of the campaign. Meanwhile there is time for the breach to widen between the two Republics of the Transvaal and Orange Free State and for Lord Roberts's proclamations to become known

One of the great difficulties which the medical service has had to contend with during the present war in a difficult country like South Africa must have been the searching for, and the stripping of the ground of, the wounded after an engagement. The battles have not been on the large scale which has taken place in many big European campaigns or in the American war and consequently there have not been such overwhelming numbers of wounded to be collected and transported to the dressing stations and field hospitals. On such occasions as these large numbers of the wounded have had to remain where they fell for many hours, or possibily even days, before any succour could reach them, *simply because it was impossible to have anything like* the necessary number of stretcher-bearers and vehicles ready to remove them and on account of the time which it takes to do so under the best possible organisation. If anyone will only take the trouble to make a calculation of the number of vehicles and stretcher-bearers and of the time required to transport any given number of wounded men any given distance from the fighting line to the rear he will realise the arithmetical nature of the problem. In the engagements in South Africa the collection of the wounded from the field has generally been well and promptly done, but there must nevertheless have been many cases where the delay in discovering and removing the wounded was considerable and unavoidable. That is one great reason for having ambulance wagons of the lightest kind consistent with safety. The British ambulance wagon is a good one of its kind, but it strikes us as providing for the accomplishment of too much and as being too heavy. An ideal system would perhaps be to carry the hospital to the wounded instead of the wounded to the hospital. That is impossible of realisation; the most that can be done is for the hospital service to put out its feelers behind and in the immediate track of the fighters in the shape of search parties and bearer columns with manual and vehicular transport, after the way in which it is now done. This is a direction in which the various Red Cross societies could be of great aid if properly organised, in addition to the various other directions in connexion with the hospital service in which they do so much admirable work. The great thing to be attained is that the regular and the various volunteer aid societies should work harmoniously together on a well-organised and well-understood system such as, we believe, is the case at the present time. Everything in war should be so designed as to be a help, and not a hindrance, to the regularly constituted branches of the service.

The somewhat sudden death of General Joubert is announced. The cause is variously given, but it is probable, from the many rumours which have from time to time reached England, that he has been ailing since the beginning of the war. We can but echo Sir George White's generous tribute to his character—a tribute rendered before he was aware of his fatal illness—"a soldier and a gentleman and a brave and honourable opponent."

THE QUEEN'S VISIT TO THE WOUNDED AT THE HERBERT HOSPITAL, WOOLWICH.

The Herbert Hospital at Woolwich, which the Queen visited on March 22nd in order to see the wounded from South Africa, was erected in 1866 and was named after Lord Herbert, the then Secretary of State for War. There are 700 beds in the main hospital and the wards are arranged four to a pavilion united by covered ways and open terraces, from designs by Captain Galton, R A Princess Christian and Princess Victoria of Schleswig-Holstein accompanied the Queen. Her Majesty was attended by Colonel the Hon. H. C. Legge and Colonel Davidson and the Countess of Antrim, Miss Emily Loch, and Sir Arthur Bigge were the members of her suite. Major-General J. F. Maurice, C.B, and the staff of the Woolwich command were in attendance on Her Majesty. On arrival at the hospital the principal medical officer, Lieutenant Colonel U. J. Bourke, R A.M.C, was presented to the Queen, as were also the following officers: Lieutenant-Colonel J. J. Lamprey, R.A M C., Civil Surgeons T. Hartington, E S B Eames, C. J. Jackson, and the acting superintendent of nurses, Miss Vaughan. Every man Her Majesty saw and spoke to was presented with a bunch of choice flowers. The Princess Christian and Princess Victoria of Schleswig-Holstein conversed with the wounded and were greatly interested On leaving for Windsor the Queen expressed great pleasure at all she saw and the arrangements made for her visit to the wounded at the Herbert Hospital.

The following telegram has been received.—

"Windsor Castle.

"To Lieutenant-Colonel Ulick Bourke, R A.M.C.

"I am desired by the Queen to express to you Her Majesty's entire satisfaction with all she saw at the Herbert Hospital on Thursday —BIGGE"

SHORT REPORTS OF INTERESTING CASES OF GUNSHOT WOUNDS FROM SOUTH AFRICA NOW IN NETLEY HOSPITAL.

The following cases serve to illustrate further our remarks on the remarkable nature of the wounds caused by the Mauser bullets.[1] Among the wounded of the Highland Brigade at Magersfontein were the following cases.

CASE 1.—Sergeant ——, of the 2nd Royal Highlanders, was wounded three times. One bullet entered one and a quarter inches below and outside the left nipple and passed out at the level of the ninth dorsal vertebra one and a half inches to the left of the vertebral column. He had hæmoptysis for eight days and his injury was followed by pleurisy. A second ball (explosive) or part of a shell brushed the side of his face and the third bullet entered the inner side of the left arm one and a half inches above the inner condyle of the humerus and passed out close to the coracoid process. The arm measures one inch less in circumference than its fellow and there is some loss of power. The patient is quite convalescent.

CASE 2.—Private —— (Royal Highlanders) was wounded by a bullet on the left side of the head over the posterior portion of the frontal convolutions. He was trephined in South Africa. He has now some loss of memory and marked slowness of thought and expression, his speech is very difficult, he has constant epiphora (more marked on the left than on the right side), and some paralysis of the muscles of the face on the right side.

CASE 3.—Private ——, of the Black Watch, was wounded by six bullets, one of which passed through the middle third of the left arm; the second bullet went through the soft parts of the back over the left scapula; the third ball entered by the left acromion process and cut its way out at the apex of the axilla posteriorly; the fourth bullet passed through the left leg and knee-joint (the motion of the joint is hardly impaired); the fifth ball passed through the left foot; and the sixth caused a flesh wound of the right calf. The patient is quite convalescent, but has partial paralysis of the left arm.

CASE 4.—Sergeant ——, of the Highland Light Infantry, was wounded by a ball which passed through the sole of the foot and severed the tendon of the extensor proprius pollicis. He has entirely lost the power of extending the great toe.

CASE 5.—Private ——, of the 1st Battalion Coldstreams, was twice wounded at Magersfontein. The first ball entered in the back over the left scapula, two inches below the spine and near the axillary border; it passed out one and a half inches below and outside the left nipple. He suffered from hæmoptysis and while he was having his wound dressed a second bullet struck him obliquely on the front of the chest over the second left costal cartilage and, passing through the soft parts, emerged one and a half inches above the right nipple; this ball afterwards passed through the lower third of the right arm.

CASE 6.—In the case of Private ——, of the 1st Battalion Suffolk Regiment, the ball struck the left malar bone and passed out at the vertebral border of the left scapula at the level of the spinous process. The ball fractured the malar bone and the lower jaw and there is now partial ankylosis of the inferior maxillary articulation.

CASE 7.—Private ——, of the York and Lancaster Regiment, was shot at Acton Homes on Jan. 20th. The entrance wound is below the outer third of the right clavicle and the exit wound at the apex of the right axilla posteriorly. The symptoms of aneurysm of the axillary artery are now present.

CASE 8.—Lance-Corporal ——, of the 2nd Battalion Wiltshire Regiment, was wounded at Colesberg. The ball entered in the tenth intercostal space in the posterior axillary line and passing through the stomach cut its way out in the middle line just below the xiphoid cartilage. He suffered from hæmatemesis for one day and had malæna for three days. The wounds were quite healed in three weeks, the exit wound being the first to heal up. When he was shot the shock swung him round, but he was able to march 1000 yards after receiving his severe injury when he was forced to lie down, feeling very sick.

CASE 9.—Private ——, of the 2nd Battalion of the Queen's Regiment, was, when lying down, struck by a bullet at Spion Kop. The bullet entered at the front of the right shoulder and emerged in the middle line of the right axilla. The brachial plexus was injured and the patient is now suffering from paralysis and loss of sensation in the hand. Both the median and ulnar nerves are affected, but especially the former.

CASE 10.—In the case of Corporal ——, of the 1st Battalion of the Border Regiment, the ball passed through the nose, the left side of the hard palate, the left tonsil, and out through the neck about six inches below and behind the ear. He was lying down when he was struck and was about 600 yards from the enemy's position at Spion Kop. The entrance wound (the scar of which can be scarcely seen) is about an inch from the tip of the nose, slightly to the right of the middle line.

CASE 11.—Private ——, of the 1st Battalion of the Border Regiment, was wounded by a fragment of shell on the right side of the head; the injury was followed by left hemiplegia which is still marked.

CASE 12.—Private ——, of the Lancashire Fusiliers, while lying down, was struck on the spine of the left scapula at the battle of Spion Kop. The ball has lodged in his body, but does not give rise to pain or inconvenience.

(NOTES FROM SIR WILLIAM MAC CORMAC.)

(Continued from p. 877.)

I arrived in Durban on my return from my second visit to Chieveley on Feb. 13th. On the following day I visited the hospital ship *Maine*. Unfortunately, Lady Randolph Churchill had that morning started off, for Pietermaritzburg, accompanied by Surgeon-Lieutenant-Colonel F. H. Hensman, A.M.S.—the senior medical officer of the ship—for the purpose of meeting her younger son, who was lately wounded near Chieveley. I was therefore unable to meet either her or the principal medical officer in charge, but the second in command (a major of the United States Army Medical Service) very kindly conducted me over the ship. Everything that could be desired for the comfort of the wounded, both from a surgical and a nursing standpoint, is to be found on this vessel. There are a large ward which can accommodate 60 patients, another for 59, and an officers' ward with 17 beds. There are a most excellent operating-room, very complete armamentarium and dispensary, and also a completely fitted x-ray room. Unfortunately, however, the ship itself is not what one could describe as suitable for a hospital. The upper deck is good, and large ports admit sufficient air, but on the lower deck the ports must often be shut. Most of the ventilation has to be carried on by electric fans (eight to every 60 patients), and there is not that sufficient cubic area or sufficient height between decks that might be expected. Lady Randolph Churchill is personally indefatigable in her attentions and kindness to the patients, as are also the entire surgical and nursing staff. Luxuries in the way of food and drink and clothing of every variety abound, practically there is nothing that "Tommy" asks for which he is not able to get, and the ship has received so many gifts in this respect that, I understand, it has become food for thought as to how these things are to be eventually disposed of. As many as 35,000 boxes of biscuits have been presented, among many other like gifts. No word could be too good for the *personnel*, the equipment, and the devoted care bestowed on the patients, but one cannot help regretting so lavish an expenditure on so inferior a hull.

After carefully inspecting the *Maine* I paid a visit to the hospital ship *Nubia*. This was my second visit to this vessel, my first having been in December last, when she was in process of being fitted up at very short notice under the direction of Captain Holland, Royal Indian Marine. This is, indeed, a beautiful vessel of nearly 7000 tons. There are ample room 'tween decks, plenty of upper deck accommodation, comfortable cots in wards, excellent convalescent cabins, good sanitation, and, in fact, after a most careful inspection, I can express nothing but the greatest admiration for the whole arrangements, and I consider that the greatest credit is due to Captain Holland and his assistants for the rapid and effective manner in which they performed the work of fitting up this ship locally at a total cost of £4500. Lieutenant-Colonel Hodder, Army Medical Service (retired), is in medical charge, and the patients enjoy the best of treatment and nursing. Captain Holland informs me that £16,000 were spent at home upon the fittings of the *Maine* and that it became necessary to spend another £1000 upon her locally on her arrival at Durban. The difference between this sum and that spent upon the *Nubia* is very noticeable.

---

[1] THE LANCET, Feb. 17th, p 485.

After inspecting the *Nubia* I and my secretary embarked upon the Union steamship *Galeka*, *en route* for Port Elizabeth, for the purpose of joining Lord Roberts at Modder River.

In connexion with this subject of hospital ships the following details, supplied to me by Captain Holland, R.I.M., are of interest. These ships have been fitted out at Durban, according to size, in from 10 to 15 days. The following vessels were fitted out by the Naval Transport Department. The *Lismore Castle*, 242 patients (21 officers and 221 men), was fitted, under much pressure, in the brief period of four and a half days; cost, £2200. The *Nubia*, 479 patients (42 officers and 437 men), was fitted in 10 days; cost, £4500. The *Avoca*, 378 patients (35 officers and 343 men), was fitted in 12 days; cost, £4000. The *Avoca* sailed for England, full, on Feb. 3rd. The cost of the same number of invalids by a mail steamer would have been approximately £10,000. Vessels such as these are much more suitable for the conveyance of invalids to England than are the mail steamers, the latter being more suitable for the accommodation of convalescents who do not require much medical attendance during the voyage.

On my arrival at Port Elizabeth on Feb. 16th the news of the relief of Kimberley by General French had just reached that place. It caused great enthusiasm in the little town. I determined to push on as rapidly as possible, and through the kindness of the traffic manager of the railway I and my secretary were enabled to start off on the same evening in a special carriage attached to a goods train. We found all the stations along the route occupied by militia detachments, nearly all the available regular troops having proceeded to the front either with General French to Kimberley or with Lord Roberts to the Orange Free State The hospital arrangements of the detachments left behind are merely those of the ordinary regimental unit, consisting of a regimental medical officer and a few hospital tents sufficient to provide for the usual percentage of cases of sickness. We reached Naauwpoort at 6 P.M. on the evening of the 17th. There were very few troops there also, General Kelly Kenny's division having moved with Lord Roberts, and along with them had gone all the bearer companies and field hospitals also We reached De Aar at midnight and pushed on at once to the Orange river, arriving there at 7.30 A.M. on the 18th. The same order of things prevailed here. A few detachments of regulars and some militia battalions only were encamped and the medical arrangements, sufficient for the local needs only, were provided for by a field hospital of the Cape Volunteer Ambulance Corps. The camp was fearfully hot and dusty, utterly devoid of grass, and dust storms prevailed to a most unpleasant extent. As our troops have been encamped in these localities for some months the sanitation is becoming a serious matter, especially as one corps relieves another very often at an hour's notice, making the difficulty of keeping the locality clean thereby much greater. We passed through Belmont and Graspan where the battles of those names were fought. These places are now, of course, on the lines of communication, and there is now nothing left to denote the fact that those fiercely contested encounters were fought there except the presence of the neatly constructed graves. The hospital arrangements all along the line from Orange river to Modder river are entirely of a local character, the idea being to convey all wounded straight through from the front by means of the hospital trains to De Aar and the other places farther down the line.

We reached Modder river about 2 P.M. on Sunday, the 18th, and were met by Colonel E Townsend, C.B., R A M C., the principal medical officer of Lord Methuen's division. The troops at Modder river at present consist of Lord Methuen's original division of 10,000 men with the accompanying proportion of field hospitals and bearer companies. Since Lord Roberts captured Jacobsdal on Feb. 14th there have not arrived any serious cases of wounds at Modder as the wounded are all being accommodated in Jacobsdal. There is no activity at Modder and a few cases of fever and dysentery only remain in hospital, so that my presence there would not be of any particular service. I therefore borrowed an ambulance wagon and, accompanied by Captain F. A. Symons, R A M C., a soldier servant, and all our impedimenta, started for Jacobsdal. We jolted across a very heavy road, forded the Modder river, and then reached a fairly level road which in some parts had even been macadamised in a modified way. About half way along we passed a deserted Free State encampment, consisting of a collection of about 20 bell tents, numbered and bearing the mark of the Free State. The tents must have been deserted in a very rapid and sudden manner. An old weary horse remained as the sole survival, quietly grubbing about amongst the short herbage for food. We completed the journey of 11 miles in three hours and I do not envy the feelings of a seriously wounded man who is compelled to travel far along one of these roads in an ambulance wagon.

On arriving at Jacobsdal we found the little square of the small town absolutely packed with bullock and mule wagons. Lord Roberts and his staff occupied the deserted house of the landdrost or chief magistrate, who had fled, and the little hotel afforded means of food supply to all comers of the commissioned ranks. The rank and file bivouacked in the open square or under the lee of the houses. I was provided with a room in Lord Roberts's house and slept there on the night of our arrival. His lordship started off with all his staff at 4 o'clock A.M. on the morning following my arrival and he persuaded me not to follow him across the open country as my services as consultant could be of no avail at the immediate front, and all the prospective wounded from the march upon Bloemfontein would be despatched to Jacobsdal and Modder river *en route* for the hospital trains. He advised me to remain at these places for a few days and then to proceed to Kimberley.

This town of Jacobsdal was only captured by us four days before my arrival. The sanitary condition is very bad indeed and I fear that disease may break out here before long unless matters can be remedied in this respect. The utmost order prevails in the town, and pickets protect the property of the late inhabitants from pillage or interference of any kind. In the square, among the many other vehicles, rests a collection of the Boer ambulance wagons. These consist of covered conveyances of all possible descriptions, and each flies a large Red Cross flag. These curious vehicles are all provided with mattresses, and although not so serviceable or clean are probably just as comfortable, if not more so, to a wounded man than our own wagons. A wonderful old stage coach and an old landau are two of the most conspicuous ambulance carriages.

The German Red Cross Society are in charge of the hospitals in the town. These hospitals consist of two churches, a school house, and four cottages, all of which fly the Red Cross and German flags. The Transvaal Government accepted the aid of this ambulance society, a similar offer having been declined by our Government. The hospital is under the direction of Dr Kuettner, who is an assistant of Professor von Bruns of Tubingen, and of Dr. Hildebrand, assistant to Professor von Esmarch. The small detached one-storeyed houses are rather ill fitted for the purpose and the walls of several of them are deeply pitted by the impact of our rifle bullets Dr. Kuettner also told me that several of our shells landed unpleasantly close to them. The patients are chiefly Boers, wounded at the battles of Magersfontein, Klip Drift, and Jacobsdal itself. A few of our officers and men were admitted yesterday from the recent engagements in this vicinity, but they will shortly be transferred to Modder river *en route* further down the line These German surgeons and their assistants have apparently been doing good work for the last three months Their medical comfort supply is now running short, particularly as their convoys from their base at Bloemfontein are now cut off by us. Their hospital will therefore in future be supplied with food materials from our medical stores In addition to the surgical hospital there is a church which is being used for medical cases, among which several typhus fever cases are present.

Affairs are on the move beyond this place in the Bloemfontein direction and nobody can say what the next few days may bring forth I append a few of the more important cases in which I interested myself which are at present lying in the hospital at Jacobsdal.

SCHOOL HOUSE.—NO. 1 WARD (16 BEDS).

1. *Injury by rock fragments.*—The patient, a Boer, was wounded at Magersfontein on Dec. 11th, 1899, by fragments of rock which were dislodged by a shell; they hit the patient in the head, causing a compound fracture of the skull To-day (Feb. 19th) a few fragments of bone were removed from the left side of the cranium over the motor area. The dura mater was found to be injured. There were also, on admission, fracture of the sixth, seventh, and eighth ribs and the inferior angle of the scapula, contusion of the left lung with emphysema of the skin and hæmoptysis, and paresis of the

right leg—not the arm. The last named symptom is now improving and the patient is convalescent.

2. *Wound of the abdomen.*—In the case of this patient, a Boer who was wounded on Dec. 11th by a Lee-Metford bullet, the entrance wound was at the ninth rib, three inches from the median line, on the left side, and the wound of exit was at the spine of the ninth dorsal vertebra on the same side about one and a quarter inches from the spinal column. The patient showed no symptoms for about 14 days, when he presented signs of a subphrenic abscess forming beneath the diaphragm. This abscess was drained from behind without resection of the rib and the man is now doing well.

3. *Wound of the abdomen.*—The patient, a Boer, was wounded at Modder river on Feb. 14th by a Lee-Metford bullet. The entrance wound was an inch behind and an inch above the anterior superior spine of the right ilium, the exit wound being an inch internal to the posterior superior iliac spine on the same side. The bullet perforated the sacrum. There were no symptoms except immediately after the receipt of the injury, when there was much pain. The patient is now doing well.

NO. 2 WARD (11 BEDS).

4. *Wound of the femoral artery.*—The patient, a Boer, was wounded on Feb. 8th by a Lee-Metford bullet. There is a wound traversing the right thigh and the femoral artery in the upper part of Hunter's canal has been injured. The limb was at first threatened with gangrene but it is now rapidly recovering. There is no sign of local aneurysm.

5. *Wound of the lung and the pleura.*—The patient, a Boer, was wounded by a Lee-Metford bullet at Magersfontein on Dec. 11th, 1899. The entrance wound was about the middle anterior border of the trapezius on the left side. Empyema of the right pleura supervened. The pleural cavity was opened up and drained and the bullet came out with the pus, being apparently free in the pleural cavity. Resection of the eighth rib in the scapular line was *performed. Hæmoptysis occurred for a few days, but no* symptoms have taken place since beyond those connected with the empyema. The patient is now convalescent.

6 *Incomplete fracture; gunshot perforation of the tibia.*—In this case the patient, a Boer, was wounded on Dec. 11th, 1899. The bullet, which entered the crest of the right tibia at the junction of the upper and middle thirds, found a point of exit posteriorly at the junction of the upper and middle thirds. It traversed the bone without causing complete fracture.

NO. 3 WARD (17 BEDS).

7. *Wound of the mouth and the lung.*—In the case of this patient, a Boer who was wounded by a Lee-Metford bullet on Feb. 14th at Jacobsdal, the entrance wound was at the tip of the tongue in the median line. The bullet came out after passing through the left lung a little below the inferior angle of the left scapula. Much swelling remains in the neck and there is hyperæsthesia in the area of the left radial nerve. There is also present hæmothorax and some hæmoptysis continues.

8 *Wound of the knee*—This was an interesting case of resection of the left knee-joint in a lad, aged 20 years. The wound, which was brought about by a shrapnel bullet at Magersfontein on Dec. 11th, 1899, caused extensive fracture. This is the only knee resection that I have seen. The limb does not appear to be in very good position, but the boy is doing well.

9. *Chest wound.*—The patient was a Boer who was wounded at Jacobsdal on Feb. 14th by a Lee-Metford bullet which caused four wounds in a transverse direction. The wound of entrance was an inch internal to the left nipple, while that of exit was an inch to the right of the right nipple. There were also two other intermediate openings, one of entrance and the other of exit, on each side of the sternum, quite close to this bone, at the nipple level. There was much hæmoptysis, which is still continuing (Feb. 19th), so probably the lung has been damaged.

10. *Wound of the patella*—This was the case of a Boer who was wounded at Jacobsdal on Feb. 14th by a Lee-Metford bullet. The entrance wound was at the centre of the left patella and the exit wound at the posterior aspect of the thigh, about four inches above the level of the articulation. There is at present a great deal of blood in the joint but there is no general disturbance and the wounds are healing.

NO. 1 COTTAGE (10 BEDS).

11. *Wound of the abdomen.*—The patient, a Boer, was wounded at Magersfontein on Dec. 11th, 1899. The entrance wound was an inch below the level of the umbilicus and slightly to the right, the wound of exit being half-way between the crest of the right ilium and the last rib, exactly in the line of the ascending colon. A fæcal abscess formed and this was followed by a fæcal fistula. The patient is steadily improving. The amount of fæcal discharge from the fistula is daily diminishing.

12. *Wound of the right temple.*—In this case, which was that of a Boer who was wounded at Jacobsdal on Feb. 14th by a Lee-Metford bullet, the entrance wound was in the right temporal region, its point of exit being through the right zygoma. The sight has been destroyed in both eyes. The patient is otherwise well.

13. *Wound of the lung.*—The patient, a private of the British Mounted Infantry, was wounded at Jacobsdal on Feb. 14th by a Mauser bullet. The bullet entered through the inner extremity of the right clavicle, which is apparently perforated without complete fracture, and emerged opposite the sixth dorsal spine three inches from the middle line on the right side. A limited amount of hæmoptysis and cough were the immediate result, but nothing else followed, and the patient is now convalescent.

NO. 2 COTTAGE (THREE BEDS).

14 *Wound of the lung and the forearm.*—Private ——, Cheshire Regiment, was wounded at Jacobsdal on Feb. 14th by a Lee-Metford bullet. The entrance wound was at the fourth rib, an inch from the sternum on the right side, while that of exit was in the mid-axillary line on a level with the right nipple. There is also a second wound of the muscles of the left forearm, paralysing the radial nerve. There were cough and dyspnœa, but no hæmoptysis.

15. *Wound of the femoral artery and vein.*—In the case of this patient, a Boer, who was wounded at Jacobsdal on Feb. 14th, a Lee-Metford bullet entered at a spot near the apex of Scarpa's triangle, wounding the femoral artery and vein and traversing the thigh. The artery and vein were both double ligatured *shortly after the receipt* of the injury and divided. Gangrene of the foot, however, has supervened and amputation of the leg below the knee will be performed to-morrow.

16. *Wound of the head and neck*—The patient, a Boer, was wounded at Jacobsdal on Feb. 14th. The entrance wound was at the tip of the nose, slightly to the right side. The bullet traversed the palate at the junction of the hard and soft portions, slightly to the left side, and emerged opposite the sixth cervical spine one and a half inches from the middle line. There is no evidence that any important structure was injured. The patient is now convalescent.

NO 3 COTTAGE (10 BEDS).

17. *Wound of the lung and the arm*—This patient was a Boer who was wounded at Jacobsdal on Feb. 14th. The entrance wound was at the inferior angle of the right scapula, that of exit being in the central line of the sternum two inches from the notch. There is a certain amount of emphysema around the exit wound, but the wound is almost healed and the patient is doing quite well. There is also a flesh wound through the left arm. There was no hæmoptysis or cough The patient is now convalescent.

18. *Wound implicating the abdomen and the thorax*—Colonel —— was wounded at Klip Drift on Feb. 16th. The entrance wound was one inch below the eighth costal cartilage on the right side three and a half inches from the linea alba in the median line. The point of exit was at the posterior border of the sterno-mastoid muscle two inches above the right clavicle. There is a fracture of the clavicle in its outer half, but this may or may not have been caused by the bullet. There is no hæmoptysis or cough, but some dyspnœa, and the patient is generally very hyperæsthetic. The bullet must have traversed the margin of the liver and the diaphragm and lung. On the 20th he had a normal temperature but there was no serious symptom and the patient only complained of the pain of the broken clavicle.

19. *Wound of the pelvis and thigh.*—This was the case of an officer in the Oxfordshire Light Infantry who was wounded at Jacobsdal on Feb. 14th. The entrance wound was one and a half inches below and externally in an oblique direction to the anterior inferior iliac spine on the left side, that of exit being at the inner side of the same thigh through the adductor longus muscle, four inches below the pubes. The vessels have escaped, but the external branch of the anterior crural nerve has been injured, causing loss of sensation.

20. *Wound of the lung.*—Private ——, Duke of Cornwall's Light Infantry (mounted infantry), was wounded by a Mauser bullet. The entrance wound was at the eighth interspace in the posterior axillary line on the left side, the bullet finding exit through the sixth rib, two inches below and external to the left nipple. There was extensive hæmothorax, but no general symptoms otherwise.

NO. 4 COTTAGE (11 BEDS).

21. *Wound of the lung.*—Private —— was wounded by a Mauser bullet at Jacobsdal on Feb. 14th. The entrance wound was at the second intercostal space, an inch to the right of the sternum, and that of exit opposite the inner border of the right scapula and two inches from its inferior angle. There was hæmothorax up to the angle of the right scapula There was no hæmoptysis or cough, but dyspnœa was present. The patient is doing well.

22. *Wound of the lung.*—The patient, Private ——, was wounded at Klip Drift on Feb. 16th by a Mauser bullet which entered opposite the fourth dorsal spine half an inch to the left of the middle line and emerged at the sixth rib in the mid-axillary line There was extensive hæmothorax but no hæmoptysis. Great dyspnœa was present. The temperature on the evening of Feb. 17th was 102° F. The patient is in a critical condition.

23 *Wound of the pelvis.*—Private ——, was wounded at Klip Drift on Feb. 16th by a Mauser bullet. The bullet entered at a point two inches below the crest of the left ilium and two inches behind the anterior superior spine and came out through the centre of the right buttock There was some tympanites. No rise of temperature There are neither fæces nor blood in the urine and no blood from the rectum. *There is no evidence of visceral injury and* the man appears to be rapidly recovering.

24. *Wound of the abdomen* —In the case of Private ——, wounded at Klip Drift on Feb. 16th, the entrance wound was close to the posterior inferior spine of the right ilium, the wound of exit being two and a half inches from the anterior superior spine on the same side in a line joining it and the umbilicus. There were tympanites and pain the temperature was 100° F. There were cough and tenderness. No serious symptoms are so far present (Feb. 20th).

25 *Perforating wound of the thorax and arm* —Lieutenant —— was wounded at Klip Drift by a Mauser bullet which entered at a point an inch to the left of the tenth dorsal spine and emerged in the mid-axillary line at the fifth rib on the right side. The bullet then traversed the upper arm outside the humerus at its middle, causing a simple flesh wound. Hæmoptysis occurred for a couple of hours *only. There was no cough or dyspnœa.* The wounds have healed and the patient is convalescent.

The wounds here noted are mainly by the Lee-Metford bullet and it will be seen that they closely resemble those produced by the Mauser bullet, the difference in weight of the two projectiles being only about three grains, the Lee-Metford being the heavier. It will again be noticed how many apparently most serious abdominal wounds are recovered from—in one of the cases mentioned above after the formation of a fæcal fistula. The chest and lung wounds are quite similar in their consequence to those of the Mauser bullet. I have now seen a very large number of cases of abdominal injury in which recovery has followed an expectant treatment and where without any reasonable doubt the intestines must have been perforated, a few in which the stomach was traversed, and two or three liver injuries. I myself entertain no doubt that in the future a perforating gunshot wound of the abdomen where from the direction taken by the bullet the intestine has almost certainly been traversed is no longer an indication of the necessity of immediate operative interference.

WILLIAM MAC CORMAC.

(FROM OUR SPECIAL CORRESPONDENT AT THE BASE.)

This has been a very busy week with everyone, as the wounded and sick from the various engagements at the front have been coming down in shoals, no less than 31 officers arriving at No. 1 General Hospital by one train. Luckily with a few exceptions the cases have been not of a serious nature; but at the same time the strain on our accommodation has been very great, as close on 100 officers alone have had to be taken in and cared for. On the Natal side it has been quite as bad if not worse, as, in addition to the number of wounded, the sick from Ladysmith have had to be accommodated. From what I can learn the majority of the cases from Ladysmith have been those of enteric fever and dysentery with a few wounded, but it will take some time before the garrison of that unfortunate city recover their normal energy. It is to be fervently hoped that any idea of still continuing Ladysmith as a camp will be strongly vetoed, especially as the sanitary surroundings are very far from satisfactory or up to date. Upon the value of its strategic position I am unable to offer an opinion, but as to its healthiness even in peace time there can be no two opinions, and the sooner it is abandoned as a military camp the better for all. The Boer prisoners have been coming down in trainfuls and are being put up on the cycling ground in Cape Town and on transports in Simon's Bay. They appeared to be a miserable, half-starved lot and seemed heartily glad to be out of harm's way and sure of a comfortable meal and a smoke.

I am sorry to say that two or three undoubted cases of bubonic plague have made their appearance in one of the transports carrying forage, the *Kilburn*, from Rosario. Immediate steps have been taken by the port officers and the ship has been removed to the quarantine ground, and all necessary precautions have been carried out. I do not at all apprehend any serious consequences, but at this time, with the harbour full of shipping, it is most unfortunate that such a *contretemps* has occurred. A great number of civilian surgeons and nursing sisters have been sent round to Natal from here, as the pressure of work there has increased to a considerable extent and their services were badly required.

The Iveagh Hospital, with Sir W. Thomson and Mr. G. Stoker, are, I believe, going up country shortly, and every vessel from England brings us more recruits for the medical service.

Sir William MacCormac and Captain F. A. Symons, R.A.M.C., left last week by the *Norman en route* for England, *viâ* Zanzibar and the Suez Canal. Sir William MacCormac's services were, of course, of the greatest value to us, and his genial manner and courtesy will cause him to be greatly missed by the officers of the Royal Army Medical Corps, with whom he was an especial favourite, not only for his well-known abilities, but for the consideration and kindly feeling which he has always exhibited towards us. A man possessing more tact and knowledge of the world it would be difficult to find, and we all trust that he will reach home safely and in good health and will be ready to aid us in our next campaign.

Several transports have left for England during the week conveying sick and wounded for Netley, and there are still a great number of officers and men waiting for conveyance. It has been the object of the authorities not to overcrowd the steamers, and nothing but *good reports have reached* us as to the accommodation and food on the voyage home. The *Majestic* arrived out last week and will, I hear, go up to Durban and thence home with a full complement of sick and wounded. Princess Christian's hospital train has gone on to Natal, as it was more required there than on this side, where we have at present three well-fitted ambulance trains running between the front and Wynberg.

The providing of a convalescent home for officers has proved to be a great boon, as it enables the hospitals to clear out those of their patients who are but slightly wounded and who are rapidly nursed and fed back to health at Claremont which has had to increase its accommodation to 60 beds during the last four weeks. I may add that there are two yachts in the harbour the owners of which have generously put them at the disposal of convalescents, sparing no expense or trouble to make their guests comfortable. *They are sumptuously* fitted and every comfort is provided, so that the wounded officer's lot is decidedly a happy one as far as Cape Town and its suburbs are concerned.

This evening we hear that the Boers are making a determined stand between Osfontein and Bloemfontein and that a big fight is coming off, so I expect our hands will be full again in a short time.

We have been having rather unusual weather for this season of the year and the rainfall has been greatly in excess of normal seasons, but *taking it all round the climate* cannot be improved upon up to the present, but later we shall not, I expect, be so fortunate, as the vicinity of the Cape during the autumn and winter is not a desirable residence for sick or wounded.

I have not touched on the subject of bullet-wounds this week, as your other correspondents keep you *au courant* with the variety of cases, but they still present the same weird characteristics as regards the courses which the bullets take.

The more one sees of them the more one marvels how these *missiles can inflict such slight injuries during their erratic* progress. After this campaign I am open to believe anything I hear about the courses of Mauser bullets as long as I am not asked to verify their stopping powers when a bone has not been struck or a vital organ reached.

March 8th.

THE HEALTH OF THE NAVY IN 1898.[1]

THE naval medical reports being almost entirely of a statistical nature are not by any means a light and lively form of literature and they lose much of their interest by not being published at an earlier date after the events to which they refer; and to the professional reader their usefulness, as it seems to us, is curtailed by their not embodying far more information of a medical character than they do. The short notes which are intercalated in the text as a sort of running medical commentary in elucidation of the figures are just sufficient to stimulate the reader's desire for more. Her Majesty's fleets go everywhere and naval medical officers have a wide and varied experience and they enjoy opportunities for gathering together a mass of instructive and interesting information such as does not fall to the lot of other men. We want to know more about the diseases and injuries from which our sailors suffer, the nature and causes of them, and the influence which climate, life at sea, and the conditions to which Her Majesty's seamen are exposed have had in their production. Something in the way of brief topographical reports descriptive of the climate, natural history, hygienic conditions, and the endemic or prevalent diseases of some of the stations visited by our naval medical officers would be of considerable and novel interest. These officers must have a good deal to write about which would not only be well worth reading but, bearing as it were an official stamp, would also be a valuable, because reliable, record of observations for future reference.

The little maps illustrative of the stations occupied by Her Majesty's fleet which are *interspersed among the leaves of the* report are, by the way, a useful feature. But we should like to see something more than a statistical report of the health of the navy, published annually, under the auspices of the naval medical bureau and compiled from reports furnished from time to time and from other data in its possession. With regard to the apparent delay in publication to which we have alluded, we recognise that this probably cannot be avoided and it is attributable to the fact that returns have to be drawn up and gathered together from various foreign stations and afterwards analysed, compiled, and compared with one another in the Admiralty at home.

The total force in the service afloat in 1898 was 82,830 officers and men. The report under notice tells us that the returns for the year 1898 may be regarded as on the whole satisfactory. The aggregate number of cases of disease and injury recorded for 1898 furnishes a ratio of 906 09 per 1000, which is an increase of 11·28 per 1000 on that of 1897, but a decrease of 60 04 per 1000 compared with the average of the previous 10 years. The increase as compared with 1897 was principally due to the East Indies station, chiefly in cases of simple continued fever, and also to an epidemic of dengue on board the *Eclipse*. The Mediterranean and the Cape of Good Hope and West Coast of Africa stations show a substantial reduction in the ratio of cases, due on the latter station to a comparative exemption from malarial fevers. The invaliding ratio of the total force was 28 86 per 1000. The death-rate was 4 91, which is slightly less per 1000 than that of 1897 and 1·94 per 1000 below the last ten years' average. This is, the report states, the lowest obtained since 1856, when these reports were first prepared in their present form. The lowest sick-rate was on the North American and West India station, and the highest on the East India station. The total number of deaths in 1898 was 407; of this number 295 were due to disease and 112 to injury. The death-rate from disease was 3·56 per 1000 and from injury 1·35 per 1000. The invaliding rate (28 86 per 1000) was lower than in 1897 but somewhat higher than the average of the last 10 years.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 33 of the largest English towns 6824 births an 4807 deaths were registered during the week endin March 24th. The annual rate of mortality in these town which had declined from 25·8 to 20·3 per 1000 in the fi preceding weeks, rose again to 21 6 last week. In Londo the rate was 20 6 per 1000, while it averaged 22 2 i the 32 provincial towns. The lowest death-rates in the towns were 10 7 in Burnley, 14·3 in Leicester, 15·0 i Huddersfield, and 15·2 in Blackburn; the highest rat were 28·6 in Plymouth, 29 0 in Halifax, 31·3 in Liverpoo and 36 7 in Wolverhampton. The 4807 deaths in the towns included 472 which were referred to the princip zymotic diseases, against 424 and 423 in the two pr ceding weeks; of these 141 resulted from whoopin cough, 123 from measles, 91 from diphtheria, 45 fro diarrhœa, 38 from "fever" (principally enteric), 3 from scarlet fever, and one from small-pox. Th lowest death-rates from these diseases occurred last wee in Brighton, Norwich, Birkenhead, Sunderland, and Gate head; and the highest rates in Wolverhampton, Salfor Preston, and Sheffield. The greatest mortality from measl occurred in Bristol, Cardiff, Wolverhampton, Oldham Preston, and Halifax; *from scarlet fever in Bradford*; an from whooping-cough in Portsmouth, Wolverhampton, Liver pool, Bolton, and Salford. The mortality from "fever showed no marked excess in any of the 33 towns. The 9 deaths from diphtheria included 36 in London, 19 i Sheffield, eight in Leeds, and four in Leicester. On fatal case of small-pox was registered last week in Hul but not one in any other of the 33 towns. Fiv small-pox patients were under treatment in the Metro politan Asylums Hospitals on Saturday last, March 24th against numbers decreasing from 11 to five at the end of th four preceding weeks, but no new case was admitted durin the week. The number of scarlet fever patients in these hos pitals and in the London Fever Hospital at the end of th week was 1715, against numbers decreasing from 3578 t 1760 on the 18 preceding Saturdays; 170 new cases wer admitted during the week, against 154, 147, and 181 i the three preceding weeks. Influenza was certified as th primary cause of 25 deaths in London. The death referred to diseases of the respiratory organs in London which had been 378 and 391 in the two preceding weeks further rose last week to 456, but were 18 below th corrected average. The causes of 67, or 1·4 per cent., o the deaths in the 33 towns were not certified either by registered medical practitioner or by a coroner. All th causes of death were duly certified in Bristol, Leicester Bradford, Leeds, Newcastle, and in 11 other smaller towns the greatest proportions of uncertified deaths were registere in West Ham, Birmingham, Liverpool, Preston, an Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns which had declined from 31·7 to 22·7 per 1000 in the fou preceding weeks, further declined to 22·2 during the wee ending March 24th, but was 0 6 per 1000 above th mean rate during the same period in the 33 large Englis towns. The rates in the eight Scotch towns ranged from 11·8 in Perth and 14 6 in Leith to 23·7 in Edinburgh an 25·2 in Paisley. The 686 deaths in these towns include 19 which were referred to measles, 18 to diarrhœa, 17 t whooping-cough, six to diphtheria, four to scarlet fever, an four to "fever." In all 68 deaths resulted from thes principal zymotic diseases, against 92 and 63 in th two preceding weeks. These 68 deaths were equal to a annual rate of 2 2 per 1000, which was 0 1 per 1000 abov the mean rate last week from the same diseases in th 33 large English towns. The fatal cases of measles which had been 17 in each of the two preceding weeks rose last week to 19, of which 13 occurred in Glasgow, tw in Dundee, and two in Paisley. The deaths from diarrhœa which had been 25 and 18 in the two preceding weeks, wer again 18 last week, and included eight in Glasgow, five i Edinburgh, and two in Greenock. The fatal cases o whooping-cough, which had been 24 and 16 in the tw preceding weeks, rose again last week to 17, of which 1 occurred in Glasgow, three in Aberdeen, two in Edinburgh and two in Paisley. The deaths referred to diphtheria, which had been five, seven, and four in the three preceding weeks, rose again to six last week, and included three in Glasgow, and two in Greenock. The four fatal cases of scarlet fever showed a slight decline from the number in the preceding week, and were all registered in Glasgow. The deaths referred to different forms of "fever," which had been nine and four in the two preceding weeks, were again four last week, and included three in Edinburgh. The deaths referred to diseases of the respiratory organs in these towns, which had declined from 362 to 189 in the four preceding weeks, further fell last week to 170, but were 19 above the number in the corresponding period of last year. The causes of 32, or nearly 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 36·8 and 31·2 per 1000 in the two preceding weeks, rose again to 35·2 during the week ending March 24th. During the past four weeks the death-rate in the city has averaged 34·4 per 1000, the rate during the same period being 19·3 in London and 22·1 in Edinburgh. The 236 deaths registered in Dublin during the week under notice were 27 in excess of the number in the preceding week, and included six which were referred to the principal zymotic diseases, against numbers declining from 12 to nine in the three preceding weeks; of these four resulted from diarrhœa, one from scarlet fever, one from diphtheria, and not one either from small-pox, from measles, from whooping-cough, or from "fever." These six deaths were equal to an annual rate of 0·9 per 1000, the zymotic death-rate during the same period being 1·8 in London and 1·9 in Edinburgh. The fatal cases of diarrhœa, which had been five, three, and four in the three preceding weeks, were again four last week. The 236 deaths registered in Dublin last week included 42 of infants under one year of age and 65 of persons aged upwards of 60 years; the deaths of infants and of elderly persons exceeded by eight and seven respectively the numbers recorded in the preceding week. Eight inquest cases and nine deaths from violence were registered, and 90, or considerably more than a third, of the deaths occurred in public institutions. The causes of 11, or nearly 5 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

The following appointments are notified:—Fleet Surgeons. G. Kirker to the *President* for three months' hospital study. Staff Surgeons: Frederick W. Stericker to the *Galatea*; V. G. Thorpe to the *Argonaut*; H. F. D. Stephens to the *Furious*; and W. J. Colborne to the Admiralty Medical Department Surgeons: S. H. Woods to the *Argonaut*; G. R MacMahon to the *Duke of Wellington*; and H. W. G. Green to Plymouth Hospital.

The announcement contained in the *London Gazette* of March 6th, 1900, of the withdrawal of Surgeon Ernest Albert Shaw, is cancelled.

THE IMPERIAL YEOMANRY.

J. Ernest Martin to be Medical Officer, with the temporary rank of Captain.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel Knox, retired pay, takes over charge of Cambridge Hospital, Aldershot, and Lieutenant-Colonel J. Martin takes over medical charge of troops at the station hospital, Londonderry.

The undermentioned officers are borne as supernumerary whilst serving with the Royal Army Medical Corps in South Africa:—

YEOMANRY CAVALRY.

Middlesex (Duke of Cambridge's Hussars): Surgeon-Captain C. Stonham.

VOLUNTEER CORPS.

Royal Engineers: 2nd Cheshire (Railway): Surgeon-Lieutenant J. R. Atkinson. 1st Flintshire (Buckley): Surgeon-Major R. T. O'Callaghan. *Rifle:* 2nd Volunteer Battalion the East Lancashire Regiment: Surgeon-Captain A. A. Watson. 4th Volunteer Battalion the East Surrey Regiment: Surgeon-Major E. J. Lawless. 2nd Volunteer Battalion the Royal Sussex Regiment: Surgeon-Lieutenant G. Black. 2nd Volunteer Battalion the South Staffordshire Regiment: Surgeon-Captain J. K. Butter. 3rd Volunteer Battalion the South Staffordshire Regiment: Surgeon-Captain C A. MacMunn. 1st Volunteer Battalion the Durham Light Infantry: Surgeon-Lieutenant A. E. Morison. 1st Sutherland (the Sutherland Highland): Surgeon-Lieutenant J. K. Tomory.

Memorandum.—The undermentioned officer is borne as supernumerary whilst serving with the Volunteer Battery in South Africa:—1st Northumberland Volunteer Artillery (Western Division, Royal Garrison Artillery): Surgeon-Captain J. Wreford.

VOLUNTEER MEDICAL STAFF CORPS.

The London Companies: Surgeon-Lieutenant E. W. Herrington. The Manchester Companies: Surgeon-Lieutenant J. W. Smith.

MILITIA MEDICAL STAFF CORPS.

Herbert Ernest Dalby to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 1st Ayrshire and Galloway: The resignation of Surgeon Captain D. Lawrie, which appeared in the *London Gazette* of Jan. 5th, is cancelled; Andrew Young to be Surgeon-Lieutenant. 1st City of London (Eastern Division, Royal Garrison Artillery): Surgeon-Lieutenant A. Allport to be Surgeon Captain. 2nd Glamorganshire: Surgeon-Lieutenant R J. R. C. Simons to be Surgeon-Captain; Ashley Bird to be Surgeon-Lieutenant. *Rifle:* 8th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Lieutenant R. C. Macdonald resigns his commission. 1st Volunteer Battalion the Buffs (East Kent Regiment): Charles Kessick Bowes to be Surgeon-Lieutenant. 3rd (Dumfries) Volunteer Battalion the King's Own Scottish Borderers: Surgeon-Captain W. D'O. Grange to be Surgeon-Major. 3rd Volunteer Battalion the Welsh Regiment: Lieutenant Alfred William Sheen resigns his commission, and is appointed Surgeon-Lieutenant. 2nd Volunteer Battalion the Queen's Own (Royal West Kent Regiment): Surgeon-Captain H. W. Roberts to be Surgeon-Major. 5th Volunteer Battalion the Durham Light Infantry; John Arthur Kendall to be Surgeon-Lieutenant. 18th Middlesex: Surgeon-Lieutenant E. MacW. Bourke to be Surgeon-Captain.

FIELD-MARSHAL SIR DONALD STEWART.

Death has been very busy of late among the ranks of old and distinguished officers. Members of both the army medical services will have heard with great regret of the death of Field-Marshal Sir Donald Stewart at Algiers. The late Sir Donald Stewart had a long and very distinguished career in India where he most deservedly enjoyed a great reputation in his military capacity and one almost equally eminent as an official of strict integrity, sound judgment, and tact. Of his military career in India and his services in the field there is no need to speak, or of the unselfish and generous way in which he stepped aside in favour of Sir Frederick, now Lord, Roberts during the Afghan War before the march of the latter to Kandahar, for these things are well known. Sir Donald Stewart was Commander-in-Chief in India, in which post he was both very popular and highly respected, and at the time of his death he was the Governor of Chelsea Hospital. We may incidentally mention that one of his daughters was married to Surgeon-Major Davies of the Army Medical Department, who died while serving in India, and that this lady subsequently married the eldest son of the late Sir William Jenner, now Sir Walter Jenner, an officer of the 9th Lancers and a member of the Staff College.

TRANSVAAL WAR NOTES.

At a meeting held in Aberdeen on March 22nd, under the presidency of Lady Aberdeen, it was reported that over £877 had been collected in the district for the establishment of a base hospital at Cape Town.

Among the subscriptions received for the Imperial Yeomanry Hospital is one of £2000 collected by Lady Harris.

The West London Hospital has placed at the [illegible] of the War Office a new ward capable of [illegible] Funds are urgently [illegible] bed[illegible]

The City of Rome [illegible]

March 23rd. She brought 232 invalids from South Africa to the Royal Victoria Hospital, Netley. The *Dilwarra* arrived with 18 invalids for Netley on March 26th.

TRANSVAAL WAR CASUALTIES.

Died from Disease.—Major James Minniece, R A.M.C., died from enteric fever at Pietermaritzburg on March 17th. Lieutenant Hall, Volunteer Medical Corps, died at Mooi river on March 20th.

The following gentlemen have joined the Army Medical School, Netley, as surgeons on probation for the Royal Army Medical Corps: A. E. Hamerton, M R C S. Eng., L R C.P. Lond., Leeds; C. H. Straton, M R.C S Eng., L.R.C.P. Lond., St. Mary's Hospital; E. P. Sewell, M.B, B C. Cantab., Cambridge University and St. Bartholomew's Hospital; and T. H. Stevenson, M.B., C.M. Edin., Edinburgh University and Queen's College, Belfast.

Sir James Reid, Bart., K.C.B., has relieved Deputy-Inspector-General H. C. Woods, M.V.O., of the Royal yacht *Victoria and Albert* in medical attendance at Windsor Castle.

"Audi alteram partem."

"THE DEFECTS OF THE MIDWIVES BILL."

To the Editors of THE LANCET.

SIRS,—On reading my address to the Islington Medical Society in THE LANCET of March 24th on the Defects of the Midwives Bill I find I have not defined with sufficient clearness the view of the General Medical Council as to the suggestion that the midwife in cases of abnormality or danger shall be required to send for a medical practitioner. The Council does strongly insist on this point. But it does not go on—as I do and as the resolutions of the Islington Medical Society do—to urge that the County Council as the local licensing and supervising authority should be required to appoint medical men to whom the midwife can apply in such cases. *The Midwives Committee of the General Medical Council* did make this suggestion in 1898, but the General Medical Council thought it involved a financial point beyond its province and simply passed the following resolution:—

> That the regulations under which licensed midwives are required to practise should include provisions securing that the midwife shall immediately seek qualified medical assistance in every case which presents symptoms of difficulty, abnormality, danger, or disease on the part of the mother or the new-born infant.

I am still of opinion that unless the Bill empowers county councils to appoint and pay medical practitioners to respond to the calls of the new midwife, with powers of recovering cost where practicable, she may often find herself in painful circumstances, or the medical profession will often have to supply gratuitously the defects of her service.

I am, Sirs, yours very truly,
J. G. GLOVER.
March 24th, 1900.

THE ORGANISM (?) OF RHEUMATISM.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of March 17th there are three papers on Acute Rheumatism of great interest. I therefore take the opportunity of pointing out that in 1891 I described in THE LANCET an organism which I had found present in the blood in patients suffering from acute rheumatism. My observations tend to corroborate the opinion expressed by Dr. A. E. Garrod that "the infection of acute rheumatism lingered on." I have observed in cases under my care that the organism continued to be present in diminished quantity—sometimes for a week or ten days after the pain and fever had subsided—and in those cases have continued the administration of the salicylate until the blood was quite free from the microbe. I have also treated cases of acute rheumatism with drugs other than salicylates and have found that whereas the administration of salicylate of soda has caused a marked diminution of the microbe in the blood examined within a comparatively few hours, the other drugs used have had apparently no effect, and in the same patient after being treated with bicarbonate of potash, antifebrin, antipyrin, &c., without effect, a few doses of salicylate would cause the rapid disappearance from the blood of
the rheumatism microbe. As my previous observa
THE LANCET passed quite unnoticed, and as I think
a very valuable guide in the treatment of acute rhe
by the observation of the blood both as to progn
treatment, I should, under your supervision, be gla
my results to the following test to prove the
ness of the discovery. Will Dr. Garrod or Dr. M
whose names would put the matter beyond suspici
me, say, half-a-dozen cover-glass preparations o
drawn indiscriminately from patients suffering fro
rheumatism (with fever) and also some from
patients? I will undertake to examine the slides
them which are the cover-glass preparations fr
healthy cases and the ones from the rheumati
patients. The slides to be all numbered unknow
in the presence of an independent witness. Being
general practitioner fond of the microscope I have
opportunity of bringing my work before the profess
in this case I consider the results of such genera
that I venture to make them prominent. Of cour
quite aware that it is one thing to find a microbic o
constantly present and another thing to cultivate i
and reproduce the disease; the latter is for obvious
impossible, and the former a very difficult and perh
an impossible matter; but it is quite sufficient for our
to find the organism in the blood increasing and d
pari passu with the disease.

I am, Sirs, yours faithfully,
EDWARD F. C
The Hall, Southwick, Sussex, March 17th, 1900.

A NOTE AND CRITICISM ON OPERA FOR THE REMOVAL OF STONE FROM THE BLADDER.

To the Editors of THE LANCET.

SIRS,—When surgeons publish their cases in the
journals, and especially when in so doing they make
statements as to the merits of one surgical proce
compared with others, they should be very careful
recommending wrong procedures they do grave mis
misleading others. The chief object that should pr
to publish our cases is that of teaching others and
our most recent experience before the world.
admitting that the profession at large owes
to the general body of hospital surgeons who g
results of their experience to their less fort
placed brethren, I fear that sufficient care is not t
prevent the publication occasionally of wrong princi
fear, also, that we refrain too often from the unco
task of refuting wrong principles and wrong teachin
we see them published.

In the Mirror of Hospital Practice at page 1
THE LANCET of Nov. 11th, 1899, is published t
lowing: "A Case of Calculus Vesicæ in a Man
53 years; Suprapubic Lithotomy; Bladder S
Catheter Tied in for 12 Days; Uninterrupted Rec
It appears that this patient was admitted to hosp
Sept. 25th. He was subjected to suprapubic lithot
Oct. 5th, an incision three inches long being made
linea alba. A soft rubber catheter was tied in and lo
for 12 days. The calculus weighed 38 grains. The
was discharged quite well on Oct. 28th, having been
month under treatment. In the paragraph introdu
record of the case the statement is made that the tr
of calculus of the bladder is at the present time in a tr
stage—a statement that I feel sure those who have ha
experience in vesical surgery will not admit. The w
the paper under reference, after recounting that 4
ago the lateral operation was acknowledged to be th
relates how lithotrity came with all its improvement
cially those of Bigelow, and later its extension to c
by Keegan and the manufacture of larger and s
lithotrites which made it possible for the surgeon
with success with any stone of whatever size or m
Then comes the portion of the paper to which I ta
grave exception: "More recently still there has been a
of the high operation of lithotomy. ...... And now th
of wounding the peritoneum, &c, has been almost b
. . . .. it is not improbable that this operation will in man
replace the crushing method; there are many argument
favour, &c." This teaching is as retrograde as it we

be. If a particular surgeon for want of experience in the use of a lithotrite or for want of the needful instruments or other cause is driven to adopt a cutting instead of the crushing method in removing a stone from the bladder in a *simple case* he has committed a sufficient surgical indiscretion without adding to it by publishing the case, and perhaps leading astray some other inexperienced surgeon situated similarly to himself.

If the above case had been subjected to litholapaxy the operation in skilled hands would have occupied a few minutes only—five at the outside. The patient would have been saved the danger, pain, and inconvenience of a wound; he would have avoided the necessity and pain of having a catheter tied in his urethra for 12 days; he would have been up and about and able to walk to his home within probably three days from the operation; he would have been subjected to an operation the mortality from which in cases so simple is almost *nil* instead of one which has a considerable mortality under even the most favourable circumstances; and he would have recovered from his malady with a normal and uninjured bladder instead of having a rigid cicatricial band in it at a part where every fibre should be capable of contraction for the proper physiological function of the organ. These advantages are very real and very important; they are such that they place the operation of litholapaxy for all cases of stone in the bladder where the conditions are suitable first and all cutting operations nowhere.

I now come to another point illustrated by this paper—viz., the relative merits of lateral and suprapubic lithotomy when one of them is necessary. Lateral lithotomy has recently been referred to on more than one occasion as difficult. Surely the difficulty is mythical. Lateral lithotomy is the safer operation of the two if the mortality following it is considered. In the majority of cases when the bladder is sutured after the high operation immediate or first intention union fails to occur, and then the urine trickling over the patient's body irritates the skin and is most inconvenient. The suprapubic method fails completely to drain the bladder as the perineal method does, and this necessity of complete drainage is one of the most important of those exceptional causes which occasionally render a cutting operation preferable to crushing.

Lastly, in lateral lithotomy the incision in the bladder is made in its fixed part and the subsequent cicatrix cannot interfere with its complete contraction for the expulsion of its contents, as a high cicatrix and especially an adhesion, may do. The suprapubic operation has one advantage, and one only, over the perineal—that it enables an inspection to be made of the base of the bladder and would admit of the simultaneous removal of a tumour of the bladder or a projecting lobe of the prostate, but cases like this are rare and would in all probability reveal themselves by special symptoms, careful sounding, and rectal examination.

Mr. T. Vincent Jackson, in THE LANCET of Jan. 6th, 1900, p. 27, after an experience of one case of suprapubic lithotomy, a selected case in a boy, aged eight years, in his remarks criticises "the rather too dogmatic and *doctrinaire* tone adopted by those who so strongly and almost as partisans advocate the modern method of treating stone in the bladder (lithotrity)." I notice these remarks here because I feel that it is possible that they may exercise a baneful influence by encouraging inexperienced surgeons to adopt this method of operating rather than litholapaxy. I can assure Mr. T. Vincent Jackson—and in this I feel sure that I shall be borne out by every surgeon of experience in this line—that it is impossible to be too dogmatic in advocating the advantages of litholapaxy over lithotomy. I hold that to subject a patient with a stone in his bladder, if uncomplicated, to a cutting operation, and particularly to suprapubic lithotomy, is retrograde surgery and might reasonably be condemned in stronger terms.

I am, Sirs, yours faithfully,
J. A. CUNNINGHAM, M.D. R.U.I., Major, I.M.S.,
Medical Officer in Charge, Civil Hospital, Delhi
March 7th, 1900.

⁂ That lithotrity as now practised is the most speedy and the safest operation in nearly every case for the removal of a calculus from the urinary bladder all surgeons will agree, but we gather from our correspondent's letter that he is opposed to the high operation of lithotomy under any circumstances. In this opinion we cannot concur; in a small proportion of cases, especially when the prostate is greatly enlarged, the suprapubic operation offers greater facilities to the surgeon for the removal of the stone than does lithotrity, and especially the surgeon is enabled at the same time to inspect the prostatic tumour and to judge of its suitability for operative treatment. The risks of suprapubic operation are now very much less than they were, and the difficulty of drainage has been fully overcome.—ED. L.

THE CONNEXION BETWEEN FEEDING AND CANCER.

To the Editors of THE LANCET.

SIRS,—Hippocrates, the father of medicine, who died 361 B.C., taught that disease might be treated by medicine, by surgery, and by diet. Medicine has had a fair trial and has been in late years almost supplanted by surgery; but there are not wanting signs that the time is fast approaching when diet will be studied as it should be and then even the surgeon will have comparatively little to do. Hitherto it has been a rare occurrence for a physician to call attention to the question of diet and still rarer for a surgeon to do so; but now both physician and surgeon do not hesitate to enter the ranks of dietetic reformers. The last to join the pioneers of the profession is Sir William Banks who, lecturing before the Medical Society of London on Cancer of the Breast, says that as the result of his researches he concludes that over-feeding is the predisposing cause of cancer; and he attributes the increase of cancer to the more general consumption of butcher's meat, the use of which has increased enormously during the last 30 years. Physicians have long taught that gout was the direct result of over-feeding and if their warning were listened to what a fell disease would be banished from our midst. Some physicians have ventured to assert that over-feeding is also the predisposing cause of all our epidemic diseases, lowering the vitality and making us an easy prey to the various bacteria which give rise to such diseases. Now that a surgeon of such eminence as Sir William Banks, after a life study of cancer, with the accumulated wisdom of close observation, has come to the conclusion that the change from the simple food of our forefathers to the highly concentrated food, more especially the fleshy food of the present day, is the cause of that dreaded disease from which in the majority of cases even the unsparing knife of the surgeon cannot save us, may we not hope that the medical profession will in these latter days turn its attention to diet, and under the guidance of Hippocrates, who has left an excellent treatise on the subject, enter upon a crusade against all foods which are known or can be proved to produce disease in man?

I am, Sirs, yours faithfully,
JOHN HADDON, M.A., M.D. Edin.
Hawick, N.B., March 26th, 1900.

To the Editors of THE LANCET.

SIRS,—Everything that tends to clear up the etiology of cancer must be of profound interest to the medical profession. But I think it may well be asked if the impressions—or would it not be better to say guesses—of even the most eminent observers do not as much hinder as promote our knowledge. Especially is this when, as in the case of Sir William Banks and Sir James Sawyer, an attempt is made to blame the consumption of meat for an increase in the cancer rate; without a single experiment or any statistics tending to show that a meat diet produces cancer, or apparently without any regard to the concurrent alterations in the habits of the people. Assuming the fact that cancer in the male is on the increase, is there not more reason to suppose with Mr. Hutchinson that it is due to increased longevity (to which, it is true, increased nourishment may assist) rather than to the increased use of meat? Upon this hypothesis might not Sir James Sawyer's observation that cancer has increased, especially amongst the masses, be explained—viz., that the masses now more often attain to old (or the cancer) age? I would submit that all the evidence at our disposal suggests that the supposed increase of cancer is due, first, to more accurate diagnosis, or at least certification, and secondly, to increased longevity.

I remain, Sirs, yours faithfully,
W. GILCHRIST BURNIE.
Bradford, March 25th, 1900.

"LEAD POISONING IN THE POTTERY DISTRICTS."

To the Editors of The Lancet.

Sirs,—The article on the above in The Lancet of March 24th, page 879, is somewhat one-sided and inaccurate in one particular (conditions so rarely to be attributed to The Lancet)—inaccurate as the Dr. Armitage—not Armytage—is J. A. Armitage of Wolverhampton and not F. F. Armytage; one-sided as the remarks made by Dr. Lewis Jones only are reported, thus leading your readers to conclude that what he had to say was the most important communication made. From a practical point of view such was not the case, the bulk of his paper being taken up by what anyone acquainted with the rudiments of electricity could learn for himself by reading a good work on medical electricity. Dr. Armitage's paper was made up of clinical material and was a description of the successful treatment of about 40 cases of lead poisoning of varying degrees of severity—one being a case of hemiplegia—and from a standpoint independent of a "current main," the source of the current being Leclanché cells, in contrast to the alternating current as used and recommended by Dr. Lewis Jones, though at a later stage in the treatment he also used the current from an induction coil. Patients were first of all treated by a general bath, both mono- and dipolar methods being used, and for local paralysis local applications with large carbon electrodes. Moreover, the meeting was really called to hear the results of the treatment of the cases under his care, seeing that they were all sent from the Potteries, one very intractable case only having been latterly under Dr. Jones's treatment at St. Bartholomew's Hospital, the result being admitted by Dr. Jones to be unsatisfactory. The discussion turned mainly upon Dr. Armitage's paper, as was to be expected from its clinical character, and as far as could be gathered from the local practitioners present—and who were primarily interested—they are indebted to him for bringing the electric bath treatment before them, and especially for the recital of so many successful cases, encouraging them thereby to put into practice his suggestions—the method being described explicitly and in detail, the appliances in the way of a bath and Leclanché's cells being available to all of them. Of the five, besides the authors of the papers, who took part in the discussion, three only are mentioned, the names of Dr. A. M. McAldowie and Dr. Allan being omitted.

I am, Sirs, yours faithfully,

Longton, March 26th, 1900. C. M. Allan.

THE FORMS AND SIGNIFICANCE OF PROTEIDS IN THE URINE.

To the Editors of The Lancet.

Sirs,—Professor Halliburton, in the remarks with which he concluded the discussion on the Forms and Significance of Proteids in the Urine at the Pathological Society of London on March 20th,[1] referred to a paper which I had read earlier in the evening. With your kind permission I should like to say a word in reply to Professor Halliburton's criticisms of my contribution. I quite fail to see how the pus present in the unfiltered urine of one of my cases could affect the results in the other seven. Albumoses were sought for in most of the urines that I examined but were found in very few and then only in small quantities. With regard to the processes which I employed for separating the proteids from the urine, I admitted in my paper that they were not *absolutely* accurate, but I am unacquainted with any other methods which would give more accurate results and could have been employed on the large scale I required. It was only after numerous preliminary experiments that I decided that Devoto's ammonium sulphate and Hammartein's magnesium sulphate methods, with due precautions, would be the most suitable.

I am, Sirs, yours faithfully,

P. J. Cammidge.

The Medical School, Leeds, March 24th, 1900.

NOTES FROM INDIA.

(From our Special Correspondent.)

The Plague in Calcutta.—Mortality Statistics for Bombay.—Plague Statistics for India.—The Protection of Simla.—Four and a half Millions on Famine Relief.—Inoculation against Typhoid Fever.

Calcutta is at last attacked by plague in real earnest. The epidemic has been developing since January and now for the week ending March 3rd 481 cases have been recorded. I understand that during the past few days a still further development has taken place and that about 100 cases a day have been returned. All the theories about subsoil water, malaria, and the character of habitations are now cast to the winds. The rate of general mortality is over 75 per 1000 per annum. The disease is chiefly prevalent in the northern parts of the city, but the most recent reports show that it is beginning to spread to other districts. There is co-existing a certain amount of cholera and to a slight extent small-pox, but it may be said that at the present time the whole of the excess mortality is due to plague. Compared with Bombay, however, the figures of plague and general mortality are comparatively small. Bombay with a population of 821 000 and 2635 deaths last week has a death-rate of over 167 per 1000 per annum; Calcutta with a population of 650,000 and 947 deaths last week has a death-rate of only 75 per 1000 per annum. In Bombay there is also raging an epidemic of small-pox which accounted for 269 deaths last week.

The plague returns for Bombay are absurdly low. There is an excess of deaths above the normal of over 2000, and yet we only find 700 deaths returned as due to plague. During the existing small-pox outbreak there have been over 2000 deaths due to this disease. On the other hand, the cost of plague has probably been during the same period over 20,000 lives. Although it is almost too late in the epidemic to have much effect it is satisfactory to find that over 4000 persons continue to be inoculated weekly, and that the total number who have been inoculated since Sept. 1st last is over 120,000. Compare this with Calcutta, where I am informed that beyond the plague workers there is practically no inoculation carried on at all. It is perhaps fair to add that no inducements seem to be held out in Calcutta for the people to be inoculated. As far as can be judged from previous outbreaks Calcutta has not yet attained the maximum of mortality for its present outbreak, whereas Bombay at the present moment may be said to be passing through those few weeks which *form* the fluctuating summit of high mortality for every outbreak. Statistics in both cities are very faulty, but the following rates of mortality in Bombay are interesting:—

	Per 1000 per annum		Per 1000 per annum.
Low Caste Hindus	383	Eurasians	84
Mohammedans	165	Parsees	44
High Caste Hindus	186	Europeans	32
Native Christians	140	Jews	31
Brahmins	103		

There is not much doubt, judging from these figures, that the rate for low caste Hindus is too high and for Mohammedans too low.

The plague statistics for the whole of India show for the week ending March 3rd 3363 deaths against 3184 in the previous week. It has already been shown how false are the returns for Bombay and how they under-estimate the mortality from plague. The same remarks apply probably to nearly all other places with the possible exception of Calcutta. There the system of recording adopted accounts for very probably the whole of the deaths from plague. In Karachi there has been a rise from 12 deaths to 47. In the Bengal Presidency there were 1936 deaths against 1905. The disease is said to have appeared in Aden and plague nurses have been despatched for service there. All arrivals from that port are said to be quarantined.

The great precautionary arrangements for the protection of Simla against plague which were in force last year are to be re-introduced with the advent of the Government establishments from March 15th. Medical inspection at Kalka will be rigid and road inspection posts will also be re-established. The special health officer is instructed to pay particular attention to the bazaars, to ascertain the cause of every death, and to take all precautions in case of death or sickness from suspicious causes Special arrangements are ordered for the surveillance of officers, clerks, and servants connected with the offices of the Government of India and their families and dependants. For 10 days after arrival at Simla all will be under observation by the local medical staff.

In addition to this increase of plague at nearly every place previously attacked India has the burden of a terrible famine. There has been a recent increase of 120,000 persons on relief and the total at the present time exceeds 4,500,000. The increase has chiefly been in the Bombay Presidency, in the Rajputana State, and in the Central Provinces.

I understand that 27 members of the first detachment of Lumsden's Horse were inoculated against typhoid fever and suffered the necessary inconvenience thereof during the first week of their voyage. From recent reports from South Africa it is a pity that a larger number were not protected, but their destination will fortunately be away from the dangerous quarters of Natal.

March 6th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Country Hospital for Chronic Diseases of Children.

THE first annual meeting of those interested in the above-named institution was held at the Town-hall on March 19th under the presidency of the Lord Mayor. The honorary treasurer submitted the financial statement, showing a credit balance of £124 on the current account and £1122 on the new building fund. The committee were looking out for a suitable site for the proposed new hospital. At present the pro-hospital is situated at West Kirby, 22 beds having been rented in the Children's Convalescent Home. As the present conditions were entirely inadequate to meet the applications for admission the committee looked for increased public support to enable them to erect a building capable of accommodating at least 200 beds. The Children's Country Hospital did not enter into competition with any existing charitable institution. It had functions of its own, such as the prolonged treatment necessary to afford cases a chance of recovery which could not be obtained in the general hospitals owing to the requirements of acute cases. It was not a cripples' home, a home for incurables, or a convalescent hospital. The hospital would become a valuable accessory to the city hospitals, two of which had received nominations to the first free beds from generous donors. Each cot now costs £25 a year, or under 10*s.* a week. A charge of a few shillings a week was made, the hospital supplying the difference. For the totally necessitous, the committee had appealed to the public for £25 a year to enable appropriated beds to be provided absolutely free to deserving cases. This appeal has already borne some fruit.

Formalin in Milk: Prosecution at the Police-court.

At the police-court last week a local dealer was prosecuted for having sold milk to which had been added formalin as a preservative. Mr. Collingwood Williams gave evidence to the effect that he had analysed the sample of new milk and found that it contained formalin. When introduced into milk formalin had the effect of retarding decomposition, and the sample in point remained uncurdled for a day longer than did ordinary milk. Professor Boyce of University College also gave evidence to the effect that the presence of formalin in milk was most injurious to the process of digestion and also to the mucous membrane of the stomach, which he had discovered by experiments on a large scale. The addition of formalin to milk also fostered such organisms as the bacillus enteritidis. The defendant, in admitting the offence, pleaded that the use of this preservative was necessary in the poor quarters where his business was carried on, as the milk was kept in the living apartment, in consequence of which it quickly became sour. The case was adjourned *sine die* upon the defendant undertaking to forego the use of formalin in future.

The Proposed Liverpool Branch of the National Association for the Prevention of Tuberculosis.

A meeting of members of the medical profession and others was held at the Medical Institution on March 21st to discuss a proposal to form a Liverpool branch of the National Association for the Prevention of Consumption and other Forms of Tuberculosis. A deputation, including Dr. E. W. Hope, the medical officer of health, and Dr. Nathan Raw, who had been chiefly instrumental in bringing the subject forward in Liverpool, was chosen to approach the Lord Mayor with the request that he should call a town's meeting to inaugurate the scheme.

The New Assistant Medical Officer of Health.

Arthur A. Mussen, M.D. Dub., D.P.H. Cantab., has been appointed assistant medical officer of health in the room of Dr. E. P. Manby, resigned. Dr. Mussen had filled a similar post at Huddersfield for 18 months.

The Foundation of a Colonial Fellowship in the School of Tropical Medicine.

A colonial fellowship of the value of £100 a year for five years has been endowed in connexion with the Liverpool School of Tropical Medicine. The generous benefactor, who wishes to remain anonymous, has stipulated that the fellowship shall only be awarded to a graduate or student of a colonial university desirous of studying bacteriology in the Thompson-Yates laboratory.

March 27th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Student Volunteers.

ON Wednesday, March 7th, a rather unusual occurrence took place in St. George's Hall, Newcastle-on-Tyne. At 3.30 P.M. 45 of the medical students of the Durham University College of Medicine marched in order under the command of Lieutenant Fullerton to St. George's Hall, where they were met by 60 students from the Durham College of Science, the united bodies being enrolled as a separate company in the 3rd Volunteer Battalion Northumberland Fusiliers (the "Fighting Fifth") under the charge of Colonel Downing. This occurrence is very unusual from the fact that the men selected their own officers and were accepted as a complete company by Colonel Downing.

University of Durham College of Medicine: Interesting Presentation to Dr. F. Page.

On Friday, March 23rd, the students of the Newcastle-on-Tyne Royal Infirmary and of the University of Durham College of Medicine entertained Dr. Frederick Page to dinner in the Hotel Métropole, Newcastle, Professor Philipson, the President of the College of Medicine, occupying the chair. About 80 guests were present, including the entire medical staff of the College of Medicine and of the Royal Infirmary and many past students. After the usual loyal and patriotic toasts, Dr. Nathan Raw, in proposing the health of Dr. Page alluded to his retirement from the hospital. Dr. Page, he said, had been not only a teacher but a friend to the students and he ranked as one of the most skilful surgeons in the country and was an ornament to his profession. The presents consisted of a candelabra, six candlesticks, and three fruit dishes, all of silver, and were given to mark the esteem and respect of the subscribers upon the occasion of Dr. Page's retirement from the position of surgical lecturer. The inscription on the testimonial reads as follows: "Presented to Professor Page by the past and present students of the University of Durham College of Medicine on his retirement from the post of Honorary Surgeon to the Royal Infirmary, Newcastle-upon-Tyne, March 23rd, 1900." Dr. Page, who, on rising, was greeted with prolonged applause, made an eloquent reply, regretting the necessity of abandoning work that he loved. The health of Dr. Ranken Lyle was proposed by Mr. Stanley Raw who welcomed him on behalf of the students as the successor of the late Dr. Nesham in the chair of Midwifery and said that Dr. Lyle had already ingratiated himself and won the respect and regard of the Newcastle students as he had previously done at the Rotunda Hospital, Dublin.

March 27th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Church of Scotland Deaconess Hospital.

ON March 21st the fifth annual meeting of friends and contributors to the Church of Scotland Deaconess

(Lady Grisell Baillie Memorial) Hospital was held in the hospital, Mr. W. T. Maxwell of Munches being in the chair. The annual report, which was read by the convener of the hospital board of management, stated that the number of patients treated during the past year was 323, as against 333 during 1893. The average daily number under treatment was 22. The number of patients treated since the opening of the hospital in 1894 was 1453 The accommodation available for patients consisted of 24 beds and four cots for children. The number of visits paid by the district nurses during the year was 3733, the average daily number of visits paid being from 18 to 20. The maternity cases which were attended numbered 33 The total sum received for upkeep during the year amounted to £1577 12*s*. 6*d*., while the total expenditure had been £1409 11*s* 7*d*., leaving a balance in hand of £168 0*s*. 9*d* The average cost per bed had been £41 12*s*. The board had offered four beds to the War Office for invalided or wounded soldiers from South Africa. The convener also alluded to the fact that the physician to the hospital, Dr. Francis Boyd, had been appointed to the staff of the Scottish South African Hospital. Professor Sir William Turner moved the adoption of the report.

The late Dr. R. H. Gunning.

The name of Mr. Robert Halliday Gunning, M.D., LL.D., Edin., whose death took place in London on March 22nd, is one which is tied by many links to Edinburgh. Dr. Gunning became a Licentiate of the Royal College of Surgeons of Edinburgh in 1839 and graduated as Doctor of Medicine in the University of Edinburgh in 1846. He always showed a very great interest in the University and was the founder of the "Gunning Victoria Jubilee Prizes" in the Faculty of Medicine. These Gunning prizes consist of 11 post-graduate prizes of £50 each. In recognition of his public services, the University conferred on him the title of Doctor of Laws.

Maternity Hospital for Dundee.

At a meeting of the directors of the Dundee Royal Infirmary on March 22nd it was intimated that the buildings for the Diseases of Women and Maternity Hospital which had been erected in the Infirmary grounds, were now completed and were practically ready for occupation. As regarded the finances of the hospital the Forfarshire Medical Association had obtained £5000 towards that object from the trustees of a large bequest. Subsequently other £5000 were raised by public subscription and then Mr. J. K. Caird, Dundee, most generously undertook to erect the whole buildings at his own expense; so that the £10,000 previously subscribed is available for endowment purposes. The buildings are believed to have cost from £7500 to £8000. Mr. Caird in handing over the buildings to the care of the infirmary directors intimated that he would give a further donation of £1000 towards the furnishing of the wards of the hospital.

The Edinburgh and East of Scotland South African Hospital.

On March 22nd the staff of the Edinburgh and East of Scotland Hospital for South Africa were inspected in the quadrangle of the old University, Edinburgh, by General Chapman, C.B., commanding the troops in Scotland. The staff left Edinburgh from the Caledonian Station on March 23rd, and received a most hearty send-off both from crowds in the public thoroughfare and from hundreds of people who had been admitted to the railway station by ticket.

The Scottish National Red Cross Hospital.

The first section of the Scottish National Red Cross Hospital, consisting of 100 beds, will be despatched to South Africa about the middle of April, if the Government can provide transport at that date. The surgeon-in-charge is Mr. Henry Olark, senior surgeon to the Glasgow Royal Infirmary, with Dr. J. Luke of the Glasgow Royal Infirmary as second surgeon. The six nursing sisters of the Army Nursing Reserve will be superintended by Miss Shannon, night superintendent at the Western Infirmary. This section of 100 beds will, on the advice of the Director-General of the Army Medical Service, be constructed in the form of tents of the tortoise pattern.

University of Aberdeen.

The Lizars Gold Medal in Anatomy has just been awarded to Miss J. O. Macleod, LL A, Roseneath, Aberdeen, being the first time in the history of the University that this distinction has been won by a lady student. Miss McLeod has also gained the vacant Mather (medical) bursary.

Aberdeen City Hospital.

The town council of Aberdeen have appointed Councillor William Boddie, J.P., as chairman of the City Hospital Committee in succession to Councillor James Fraser who recently died suddenly in one of the baths at the Corporation Baths, Aberdeen sea-beach.

Aberdeen Medical Staff Corps.

There are now 150 of all ranks of the Aberdeen Company Volunteer Medical Staff Corps which is in excess of the authorised establishment—namely, 133. No more recruits are therefore being admitted at present. The corps is now fully equipped for the field. The officer commanding (Surgeon-Captain J. Mackenzie Booth) has requested non-commissioned officers and men to volunteer to join the Royal Army Medical Corps for service in South Africa or for home service.

March 27th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Dublin Public Health Inquiry.

THE committee appointed to inquire into the causes of the high death-rate of Dublin concluded their sittings on March 22nd and proceeded to consider their report. Sir Charles Cameron, the superintendent medical officer of health, volunteered some supplemental evidence on matters already dealt with during the inquiry. Referring to the evidence of Dr. Katharine Maguire he stated that there was no doubt as to the meritorious work in which the ladies of the Alexandra Guild were engaged and he had given instructions to the sanitary officers to assist them as far as possible. In reply to Dr. Moore, the President of the Royal College of Physicians of Ireland, Sir Charles Cameron stated that in his opinion intramural interments in vaults of churches were distinctly objectionable and dangerous to the public health. In some cases he had seen coffins blown up by the gaseous products of decomposition, and he understood that in some instances small openings were made in order to prevent this result He looked upon the system as a barbarous one. Mr. Henry Campbell, town clerk of Dublin, in his evidence condemned the insanitary condition of some of the schools in the city connected with the National Board of Education. He mentioned the case of a school where 500 children attended daily in a building which was damp and cold and in which the roof and walls were wet. The evidence is interesting as it corroborates the statements recently made by Professor Roche in an article in THE LANCET. The investigations of the committee have now come to a conclusion and they have before them a large mass of evidence on which to found their report. It seems to your correspondent noteworthy that although the high and long persistent rate of mortality from typhoid fever was made clear no inquiry was instituted into the method pursued for the disinfection or destroyal of the typhoid fæcal dejecta in the large fever hospitals or in connexion with isolated cases. The evidence as to insanitation, overcrowding, dirt, &c., does not seem to offer a sufficient explanation, for it has been long notorious that enteric fever has prevailed widely and claimed many of its victims, not from the slums, but rather from the wealthy, least-crowded, and best quarters of the city.

Commissioner of Education in Ireland.

His Excellency the Lord Lieutenant has appointed Sir Francis Cruise, consulting physician to the Mater Misericordiæ Hospital, to be one of the Commissioners of Education in Ireland.

Royal College of Surgeons in Ireland.

The Royal College of Surgeons in Ireland occupies a foremost place among the crowd of public bodies in Dublin who wish to offer a suitable welcome to Her Majesty. The college buildings with their handsome frontage of cut stone will present a fine appearance when the present elaborate scheme of decoration and illumination has been completed.

The Gas-Lighting of Dublin.

Under the heading "Change in the Composition of the

Dublin Gas Supply" a rather startling statement has recently appeared in the public papers from Professor Emerson Reynolds, F.R S , of Trinity College, who, in a lecture there, pointed out that an important change had just taken place in the city gas supply, consisting in the addition of a considerable proportion of what is technically called "water-gas" to the ordinary product from coal. Ordinary coal-gas contains about 6 per cent. of the deadly poisonous carbonic oxide to which it owes chiefly its own poisonous effects when respired. Water-gas contains from 30 to 40 per cent. of that poison. Its addition to the ordinary lighting gas of the city raises, therefore, the proportion of carbonic oxide and consequently renders the city gas more than usually poisonous. Professor Reynolds explained in detail how the change was noted and its extent measured. 12 analyses of the city gas were made in the College laboratory between Nov. 25th and Feb. 16th, the mean results of those analyses proving that the average coal-gas contained 6 2 per cent. of carbonic oxide. A subsequent series of analyses shows that the proportion of carbonic oxide increased steadily until it reached 12 6 on March 7th. The analysis of March 12th showed a proportion of 17·9 per cent , but on March 17th it stood at 10 6 per cent. Professor Reynolds concluded by saying that there was no reason for undue alarm or for assuming that the addition of water-gas to coal-gas was not legitimate provided that the mixture maintained by carburetting the standard value of 16 candles. "I think," he said, "however, that the fact of so material a change in the nature of the supply should have been notified to consumers in order that they might be on their guard against escape of the new gas through defective fittings or by imperfect combustion from flaring on unsuitable jets."

The Water-supply and Drainage of Newtownards.

The Local Government Board have written to the Urban Council of Newtownards requesting them to take steps to provide the urban district with a sufficient supply of good, palatable water without further delay, and also to obtain the services of a qualified and experienced engineer for the preparation and carrying out of a new sewerage scheme for the district.

The Union Society of Queen's College, Belfast.

The annual report presented on March 23rd at a business meeting shows that financially there is a slight balance. The total receipts were £296 10*s.* 6*d.*, of which £131 13*s.* 9*d.* were obtained from the billiard-room and £56 11*s.* 9*d.* from tobacco sold in that place. The profits on the sale of tobacco were £8 12*s.* 3*d* There are 159 members now on the roll.

The Close of the Medical Session at Belfast.

The winter medical session for 1899–1900 comes to a close this week (March 31st). The examinations in medicine of the Royal University will begin in Dublin on April 18th and will, it is expected, be completed in time to allow those members of the Belfast medical school who are engaged in them to commence the summer session on May 1st.

March 26th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Paris Water-supply.

AT a meeting of the Municipal Council of Paris held on March 15th several resolutions were passed with a view to increase and improve the quality of the supply of drinking-water to Paris. It was resolved to acquire a tract of land for the purpose of supplying the aqueduct of Loing with an additional intake. It was also resolved that an inquiry should be undertaken as to the existence of springs and underground supplies of water so as to complete the supply of the aqueduct of the Dhuys, and that a stationary analytical department should be organised at the head waters of the Arve and the Vanne or, if this were not feasible, that a flying analytical department should be formed.

Kleptomania in a Medical Man.

A Doctor of Medicine was recently summoned before the Tenth Correctional Chamber of the Tribunal of the Seine on a charge of theft. In the month of February he had on two occasions opened the till of his hairdresser and had each time abstracted 20 francs. On Feb 6th, at the moment of again yielding to temptation, he was arrested and at once taken before the Commissary of Police, to whom he confessed his guilt. He was not taken before the magistrate but was condemned to eight months' imprisonment At the Commissariat of Police he declared that he could not explain the motive for his act. The case is all the more inexplicable as he is very well off.

An Epidemic of Septicæmia among Children at Nurse.

At the meeting of the Hospital Medical Society held on March 9th Dr. Lesage gave an account of a most interesting form of septicæmia which he had observed as affecting children at nurse. It is very acute and its course so rapid that in a few hours the temperature runs up to 40° or 41° C. and death supervenes in a very short space of time. There is intense dyspnœa although auscultation reveals nothing wrong with the respiratory apparatus. The patient is obviously very ill, presenting a pale, anxious appearance, with great dryness of the tongue and lips. The child occasionally give a half stifled cry, is very drowsy, and sometimes has slight diarrhœa. Death rapidly supervenes but no definite lesion is found post mortem. Microscopical examination of the bronchi, however, shows the presence of streptococci. Facts of special interest in the cases noted by Dr. Lesage are the finding of pneumococci in the bronchi and the epidemic nature of the malady. In one hospital 16 cases occurred in five days and 15 of the patients died. The infection appears to be conveyed by nurses. The illness lasts from a few hours to two or three days, and its clinical course is the same as that of the septicæmia described by Hutinel. The epidemic died out for want of patients, and at its termination the wards were disinfected and everything settled down again. Dr. Lesage considers that these facts prove that a nurse-child is very easily affected by the pneumococcus as well as by the streptococcus, and this extreme sensitiveness brings about a general septicæmia before the tissues of the organism have time to erect a defensive barrier and so confine the infection to a local manifestation.

The Examination for Hospital Appointments.

The public examinations of the Assistance Publique seem fated always to be marked by some "incident." An examination was held recently for the nomination of six hospital physicians and was conducted under the new regulations which I have already described[1]—that is to say, there are 12 judges, and after the testing of each candidate every judge writes his opinion upon a piece of paper which is folded up and the opinion is given by the writer without any consultation with his colleagues. At the end of the examination the voting-papers are arranged in a decreasing order and one candidate is selected. In this instance the examination had already begun when one of the judges, Dr. Wurtz, discovered that one of the candidates was his cousin eight times removed. Dr. Wurtz therefore asked the authorities of the Assistance Publique whether owing to this circumstance there was any danger that later the election might be rendered invalid. It was considered that Dr. Wurtz would do better to retire from the jury. This of course left only 11 judges instead of 12 and then the question arose as to whether this did not annul the whole procedure and whether another jury should be elected. The political press took the matter up and clamoured for a new jury, arguing that out of 11 the majority would be six and hence that as there were six places to give away it would be quite easy for six of the judges to work matters so that every one could return his own candidate. They even went so far as to give the names of the six who were sure to be elected. The scandal, however, is very slight, for both the judge and the candidate were quite ignorant up to the time of the examination of any connexion between them and the candidate resigned at the same time as his judge. But the accuracy of the details furnished by the public press proves conclusively that these latter derived their information from other candidates who were jealous or discontented with the position they had attained and so wanted a new jury and a new election so as to get another chance. The incident is regrettable as showing the personal nature of the feeling at these elections. Although the judges forming the jury are drawn by lot, once its composition is known it is easy to forecast results. The relations of a pupil to his master have much more influence upon impartiality than cousinship in the eighth degree. It is quite evident why under these conditions candidates who do not see their teachers chosen by lot on the jury should wish to have the drawing over again. Some time ago certain waggish candidates suggested that the examination should simply be confined to the drawing of lots.

March 27th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

An Army Medical Officer on the War in South Africa.

DR. KRUMMACHER, one of the German army medical officers who were sent to the scene of war in South Africa as medical attachés to the British army, has now returned to Germany and has published his impressions. He highly praises the sanitary arrangements of the British army. The tents carried with the troops proved extremely valuable at Magersfontein, where the soldiers suffered much from the hot days and the cold nights. The British suffered more from the rifle fire of the Boers than from their artillery fire, the Boers being unequalled as marksmen. They used to aim at the officers, who were easily recognisable by the brightness of their uniforms. Afterwards in the course of the war the uniform of the officers was made to resemble that of the men. It was very remarkable that the Boers never fought at night. At sunset they used to stop firing and retired even when they had gained a favourable position. As to the alleged abuse of the Red Cross, of which there were so many complaints in the newspapers, Dr. Krummacher states that he never saw anything of that kind. The ambulance to which he was attached was sometimes fired upon by the Boer artillery, but only when it stood in the neighbourhood of a body of troops, so that it was probably the latter that were aimed at. The British troops once captured a Boer ambulance because the ambulance men were accused of having fired on the British. When this report had been proved to be erroneous the ambulance was at once sent back to the Boers. The medical attachés will submit a detailed report of their observations to the German military authorities.

The Title of "Sanitatsrath."

A remarkable law-suit has lately been before a court at Marburg arising out of the bestowal of the title of "Sanitatsrath" (sanitary councillor) on a medical practitioner in that town. It is the custom to grant this title to nearly every medical man of respectability and good professional standing after he has been engaged in practice for a period of from 20 to 30 years. This title is not connected with any Government appointment, but is a mere personal distinction like so many others in this country, where people are, as a rule, rather fond of titles. The medical man in question was quite pleased with his new dignity, but when the diploma was delivered to him he was mortified on finding that he had to pay a stamp duty of 300 marks (£15) according to the Stamp Laws of 1895. He paid the duty but afterwards brought an action against the Treasury to have this sum restored on the plea that he had not been asked beforehand by the Government whether he desired to have the title or not. He asserted that he had gone to law with the Treasury solely in the interests of the medical profession, as it was in his opinion unjust to charge a medical man for a title whilst the Government accepted the gratuitous services of the medical profession in so many cases. The decision was in the plaintiff's favour, but in view of the fundamental importance of the matter the Treasury has appealed to the High Court where this curious incident will be definitely settled.

The Case of Professor Neisser.

Some experiments on immunisation against syphilis, made by Professor Neisser the well-known dermatologist of Breslau, have recently been the subject of discussion in the Prussian Diet. The facts of the case, which have been misunderstood by the adversaries of scientific research both in Parliament and in the daily press, are briefly as follows: Professor Neisser injected sterilised blood-serum of syphilitic persons into prostitutes and into two children in order to immunise them against the disease. The experiment had no bad sequelæ whatever. Several years afterwards some of the prostitutes suffered from syphilis, which first manifested itself on the genitals, so that the attempted immunisation had proved a failure. That they had been infected by the injection, as was alleged by Professor Neisser's adversaries, was quite impossible owing to the length of time between the giving of the injections and the appearance of the syphilis, together with the fact that none of the patients other than the prostitutes contracted the disease. These facts were gravely misrepresented by different speakers, Professor Neisser being said to have injected syphilitic virus in order to see whether it was contagious or not. Several members of the Diet asked the Minister of Public Instruction if Professor Neisser had been or would be prosecuted for what he had done. The Minister, Dr. Studt, and the Chief of the University Department, Herr Althoff, stated that Professor Neisser had not performed his experiments for frivolous reasons, but for the eminently humane purpose of combating syphilis. They said that he no doubt erred in making experiments on patients without previously asking them whether they consented to the injections or not. The Minister admitted that he might have been prosecuted under the criminal law, but as the acts complained of were committed six years ago there was, under the circumstances, no likelihood of a prosecution. The Government had not yet considered whether it would be advisable to make use of its disciplinary power over him as a professor of a State University. Professor Virchow, as a member of the Prussian Parliament, said in the debate that every new method must necessarily be used as a new method at least once on the human subject after it had been tried on animals. He said that Dr. Edward Jenner, Professor Koch, Professor Behring, and other men of science who had done so much for the prevention of diseases had all made experiments under the same conditions as Professor Neisser. The Minister, Dr. Studt, closed the debate by asking the members of the Diet not to indulge in denunciations of the medical profession in general, which had distinguished itself by its devotion to the interests of the State and ought to serve as an example to other citizens. The leading medical papers protest strongly against the unfriendly manner in which some members of the Prussian Diet spoke on the subject of medical men and medical science. They, however, blame Professor Neisser for having subjected his patients to this treatment without their consent. The matter is not yet finished, but it is very unlikely that the Government will take any steps against Professor Neisser.

March 26th.

SWITZERLAND.

(FROM OUR OWN CORRESPONDENT.)

The Swiss Army.

ACCORDING to official reports the strength of the Swiss army on Jan. 1st, 1900, was as follows: 1. "Auszug" (men from 20 to 32 years of age), 150,876 men, comprising 113,617 infantry, 4551 cavalry, 20,442 artillery, 5586 engineers, and 4928 in the sanitary corps. 2. "Landwehr" (men from 33 to 45 years of age), 87,364 men, a well-armed and well-trained militia, making with the Auszug a total of 238,240 men. In case of war the youths from 16 to 20 years of age would also be available as some 6000 of their own free-will receive military instruction, generally on Saturday afternoons and Sunday mornings; then part of the "Landsturm" (men over 45 years of age), making a total of 277,007, would also be available and would be of great use for defensive purposes and for keeping up communications. General conscription was introduced many years ago, but only about half of those presenting themselves for medical examination are annually accepted, the percentage being 52·4 in 1898 and 51·8 in 1899, or a number of 16,773 men (1899) The obligatory military service is seven weeks in the first year, six weeks in the second year, and about three weeks every two years up to the age of 32 (Auszug); afterwards in the Landwehr, up to 45 years of age, only a few weeks' service every three or four years. Officers have to do about five months' service before they obtain their commissions. Men excluded from service by the medical authorities have to pay a high military tax consisting of capitation tax, income property tax, tax on expected property—viz., property the men are legally entitled to from parents, grandparents, or other relatives The enforcement of this tax is only possible owing to the fact that the Swiss civil law obliges the citizens to leave their property in certain legally determined parts to relatives in the first and second degree Thus a father can only dispose of one tenth of his property as he chooses, nine *tenths must go to his children* In this way the authorities have control over property in expectation and curious results ensue A man of wealth may find himself, as a grandfather, obliged to pay a heavy military tax for his grandson who happens to be studying law or medicine and on whom a large sum as military tax is levied The alternative for the man is to serve in the military offices as clerk at 1*s* 8*d* a day to pay off such a debt

Cerebral Complications due to Intestinal Infection

Dr T Seitz of Zürich, sums up 15 such cases five of which are recent unpublished cases, permitting of interesting deductions the cases having gone through the most thorough bacteriological investigations No doubt an invasion of the blood and lymphatics by intestinal bacteria now and then takes place and obscure cerebral disease may result In seven out of the 15 cases bacteria of the intestines could be definitely and decidedly proved to be the originators of the cerebral disease The only cause for wonder is that the protective apparatus must work almost perfectly, given the enormous amount of intestinal bacteria otherwise such cases would be far more frequent In fatal cases the post mortem examination fails to confirm the clinical diagnosis of meningitis or encephalitis apparently established beyond doubt and only the most careful bacteriological examination reveals the existence of some few staphylococci streptococci, or bacteria coli, the toxins of these bacteria must therefore play a more important rôle than the bacteria themselves In some cases infantile convulsions and sudden death are *certainly* due to this mode of infection

Zürich, March 24th.

NEW YORK

(FROM OUR OWN CORRESPONDENT)

Medical Instruction in the United States

THE system of medical instruction in the United States has for several years been undergoing a very remarkable change The method of teaching classes by oral lectures has until recently been universally practised No effort was made to classify the students according to the length of time during which they had studied In the same lecture room and listening to the same professor were one-year, two-year, three year, and four year men and as a matter of fact not one in 10 received any real instruction There was a medical college at one period which had but one professor who lectured on the seven branches But in the best schools the system has entirely changed and this change is due to the union of those schools with universities which has led them to adopt the methods of teaching peculiar to those institutions It is true that the medical department of the University of Virginia has classified its students for many years and taught by recitations in small classes, but the number of students has been very small and its example has not influenced the larger metropolitan colleges It has long been recognised by examining boards that candidates from the Virginia College, as a rule excelled those from other colleges, especially in technical knowledge It was not until within the last decade that the larger colleges became thoroughly incorporated into the university systems of government and this new position has led to important changes in the details of management which appear most markedly in the methods of teaching The old lecture system has been entirely abandoned as a scheme of general instruction and is limited to the higher branches which require for their proper elucidation the knowledge and experience of the professor Classes are arranged on the basis of the advance of the students in knowledge into those for one-year, two year, three year, and four year men For each of these grades assistant professors or tutors are provided and class recitations are held the text books being uniform No student can advance from a lower to a higher class who has not attained a given grade of qualification Under the old system the student was rarely questioned on any subject and there was no educational barrier to his advance In the case of most students the first individual contact of the teacher with the taught was at the final examination for graduation Now the student is daily required to demonstrate to the teacher his exact status in his studies and at the termination of fixed periods his markings during the term are the tests to determine whether he can advance to a higher grade The results of this rational method of teaching are most important The graduates from these university medical schools take the highest rank in their profession wherever they locate It is gratifying to notice also that these higher grade colleges which were at first shunned are now becoming more and more popular and their classes are yearly increasing in members The more progressive of these schools have recently established educational qualifications for admission which require graduation from a literary college

The Death of the Author of the "Gold Cure" of Alcoholism.

The death is announced of Dr Keeley, the author of the notorious "gold cure of alcoholism For many years this method of treating inebriety has had an enormous popularity and institutions devoted to the "cure' have multiplied in every State The central office was at the village of Dwight in the State of Illinois which was a veritable Mecca of the victims of delirium tremens The remedies used were kept a profound secret and each patient had to take his dose directly from the physician in attendance The results of inquiries in regard to the true success of the treatment were all negative I at one time investigated cases of reported cure but found none that had not relapsed after they had returned to their old haunts There is no doubt that some did abstain for a long period as was the case with the converts to teetotalism during the crusade of Father Mathew the famous Irish temperance lecturer Though the craze after the 'gold cure has long since passed there are many institutions in the different States which continue as a business enterprise, for immense sums of money have been made by the promoters of the supposed ' cure '

The Farm Colony for the Insane

The question of providing an economical method of caring for the chronic insane has agitated those interested in treatment of this class for many years, but has not until recently taken any other practical form than the introduction of a few trades into existing asylums In two of the States asylums for the chronic insane have been established separate from the asylums for the acute but no useful results have followed because the same methods of care have been continued in the chronic as in the acute Many efforts have been made to introduce the boarding out system of Scotland but the managers have strenuously objected, alleging that the people of this country are not adapted for such duties Several of the States have within the last decade encouraged their asylum managers to experiment with farms and the result has been so encouraging that the subject of establishing farm colonies for the chronic insane is attracting much attention In Michigan a farm colony was established many years ago and the success has been twofold—viz financially the farm has paid richly and a far larger number of chronic insane have recovered than under any former conditions At Utica the experiment is in progress and the latest reports of Superintendent Blumer show a most encouraging success The plan proposed is the creation of an organised community with all its trades farm labour and products being the central feature, because by far the larger number of the population must necessarily be engaged in farm work Should this method of caring for the chronic insane continue to succeed there will be a complete revolution in our institutions for the insane and greatly to their advantage

Indigence in Porto Rico

Major Hoff of the *United States Army* and President of the Porto Rico Board of Charities states in his report that in a population of 956 779 there are over 80 000 persons requiring assistance and that from 400 000 to 600 000 rations are issued weekly Those who can work for their rations are required to do so and these number upwards of 9000 There is an average of 4000 sick The immediate suffering in Porto Rico is due to the severe hurricane which desolated the island destroying not only all the crops and a vast number of dwellings, but maiming and killing large numbers of people

Tenement House Exhibition

New York has lately been entertained with an exhibition of model tenement house plans prepared for competitive examination. It originated with the Charity Organisation Society, the object being to awaken an interest among the wealthy in the efforts of that society to improve the tenements of the poor by constructing a class of better dwellings which will, when properly managed, return a fair income to the owners. The exhibition included models, plans, photographs, maps, charts, and tables of statistics. They were designed to show existing conditions in New York tenement houses, model tenements all over the world, suburban dwellings, lodging-houses, health conditions, poverty conditions, agencies for betterment, and finally the competitive plans for model tenements, parks, and playgrounds. One of the most interesting group of photographs illustrated the evolution of the New York tenement house on the usual 25 feet by 100-feet lot. First was the common dwelling-house occupying 50 per cent. of the lot, four storeys and basement, three rooms with closets on each floor above the parlour floor; next the same building is converted into a tenement house, requiring in the same space two living rooms, six bedrooms, hall and stair way; then appears the same building, but on the rear portion of the lot another has been erected with one living room and three bedrooms, and now 75 per cent. of the lot is occupied, while the number of tenants has been increased at least 33 per cent.; finally, the modern tenement rises to view covering 90 per cent. of the lot with its dark, unventilated sleeping rooms and a population of 100 persons where at first there were but five. There were also illustrations of English model tenements—viz., amongst others dwellings erected by the Peabody Donation Fund, those of the South London Dwellings Company, the Four Per Cent. Dwelling Company, the Guinness Trust, and a group representing Miss Octavia Hill's work, with a reproduction of Sargent's portrait of Miss Hill. For one week the society held a series of meetings at which eminent speakers discussed in public all the phases of the improved tenement house movement. Upwards of 300 plans were submitted to the jury appointed to adjudge awards. The exhibit will be sent to the Paris Exhibition, after which it will find a permanent place in New York.

Illness being an Act of God justifies a Breach of Promise.

A curious case of breach of promise, where the defendant alleged an intercurrent disease for which he was not responsible as his defence, has recently been decided by the Court of Appeals of Virginia. It appears that after the engagement and before the time fixed for the marriage the defendant had without fault of his own developed and was suffering from a grave malady involving the urinary organs, viz., cystitis, with probable inflammation of the urethra, complicated with enlargement of the prostate. He had been advised and believed that sexual indulgence would aggravate the disease and would be likely to shorten his life; that it would be not only a wrong to himself but an injustice to the plaintiff if he married her in his condition of health. The court held that "illness" is an act of God and beyond the power of man to control or prevent, and that if the performance of a contract is rendered impossible by the act of God alone such fact will furnish a valid excuse for its non-performance, and such a stipulation will be understood to be an inherent part of every contract. Marriage is assumed in law to be for mutual comfort, and being satisfied from the evidence that the defendant acted throughout with good faith the unhappy circumstances in which he found himself justified the alleged breach of his contract to marry the plaintiff.

March 18th.

CARDIFF PORT SANITARY AUTHORITY.—The medical officer of health to the Cardiff Port Sanitary Authority (Dr. E Walford) in his annual report for 1899 states that the floating population of the district is estimated at 7000 persons, contained for the most part in the West Bute, East Bute, and Roath Docks, Cardiff, and Penarth Dock and Tidal Harbour. During the year 11 patients were admitted to the Cardiff hospitals for infectious diseases; eight of these were cases of typhoid fever and three proved fatal. 7170 vessels were inspected and of these 1597 were found to be in a defective or insanitary condition. The frozen meat trade of the port is a large industry and the inspection of such meat forms part of the duty of the inspector. In the year 16 cargoes arrived with about 7000 carcasses of beef and 150,000 carcasses of mutton. 2167 head of live cattle and 1318 live sheep were landed from Montreal and Quebec.

Obituary.

ROBERT CORY, M.D. CANTAB., F.R.C.P. LOND.

WE have briefly recorded the death of Dr. Robert Cory, which occurred on March 19th. This followed directly upon an illness of some weeks' duration only, but during the latter part of his life his health was by no means good.

Dr. Cory was a Cumberland man and was born in 1844. He received his medical education at Cambridge, at the ancient College of Pembroke, where he graduated with honours in the Natural Science Tripos of 1868. Three years later he took the degree of Bachelor of Medicine, proceeding in 1879 to the M.D. On leaving Cambridge he entered at St. Thomas's Hospital where, after a successful career as a student and as a member of the junior staff, he became assistant obstetric physician, lecturer on forensic medicine, and physician in charge of the vaccination department. Dr. Cory will be chiefly remembered for his excellent work in the last direction. For 25 years he was engaged in the practice and teaching of vaccination, the lectures which he delivered to his pupils on the subject contain masses of accurate information, while he himself fell a victim to the ardour of his scientific researches.

As far back as 1881 he was associated with Sir George Buchanan in the founding of the Government Animal Vaccine Establishment, and since that date until his death he acted as its director. He was not only a teacher of vaccination but an exceptionally expert operator. The correctness of the latter statement may be gauged from the fact that in the report of the medical officer to the Local Government Board for 1887 he was able to put on record the fact that in the case of over 38,000 primary operations with human or with calf lymph only in one instance had he failed twice at an attempt at vaccination. With the exception of this case, in which he had an opportunity of making a third attempt, he had never met with a case of true "insusceptibility." Since 1887 the number of consecutive primary vaccinations performed at the Government station by Dr. Cory, or under his auspices, has mounted up to a total of 110,728, and still without the occurrence of a single case of insusceptibility.

Dr. Cory's great enthusiasm in all matters connected with vaccination led him, about 30 years ago, to carry out a series of experiments dealing with the possibility of the conveyance of syphilis in the operation of vaccination. Believing that the results of these experiments were likely to be of service to the medical profession he did not hesitate to offer himself on the altar of science, and on four separate occasions deliberately vaccinated himself from the clear lymph, free from obvious contamination with blood, of vaccine vesicles on the arms of children who were undoubtedly suffering at the time from syphilis in active form, as shown by the presence of cutaneous eruption, snuffles, mucous tubercles, and ulcerations. On the first three occasions on which Dr. Cory thus experimented on himself no syphilitic trouble followed the inoculations, but at the fourth attempt the result was only too successful, an exceptionally severe attack of the disease having supervened, the effects of which appeared, unfortunately, to persist to a certain extent for the remainder of his life and not improbably were concerned in bringing about his death at a comparatively early age.

It was mainly in recognition of the heroic self-sacrifice involved in these investigations that the British Medical Association conferred the Stewart Prize on Dr. Cory in 1886. As typical of the natural modesty and retiring nature of the man may be mentioned the fact that on this occasion he refused to attend in person for the presentation of the prize. Among other important researches Dr. Cory carried out a long-continued series of observations on the relation of protective vaccination to the development of the vesicle, reading a paper on this subject before the Epidemiological Society in 1879. 20 years later he published a volume entitled "The Theory and Practice of Vaccination" in which he set out his more matured observations on this and other aspects of the vaccination question. This volume, the separate chapters of which represented a series of lectures which Dr. Cory was wont to deliver to his class at St. Thomas's Hospital, was reviewed in these columns shortly after its issue, but, nevertheless, it may not be unfitting here to call attention more particularly to a series of micro-photographs forming one of the plates with which the volume is embellished. These represent sections of a small-pox vesicle, a vaccine vesicle, and a syphilitic chancre respectively, the portion of tissue from which the latter was cut having been removed from Dr. Cory's own arm at the time of his much-to-be-regretted personal experiment. The figures in this plate (No. 4) form a convincing argument in opposition to the tenets of certain members of the profession who hold that a definite relationship exists between the two diseases, vaccinia and syphilis The careful examination of Dr. Cory's sections will at least show that those who hold this opinion cannot have studied the matter from the histological point of view or they could hardly have failed to appreciate the fact that, as pointed out by Dr. Cory, the microscopic appearances of the skin lesion in one and the other affection are absolutely distinct.

Space does not permit of reference to numerous other points in relation to vaccination investigated by Dr. Cory, but in conclusion it may confidently be affirmed that not only have his example and ready assistance greatly aided the efforts of other workers in this field, but that the results of his own personal labours have been of no little value and assistance, more particularly to the Department he faithfully served for so long a period.

HIS EXCELLENCY ROBERT HALLIDAY GUNNING, M.D., LL.D. EDIN.

ROBERT HALLIDAY GUNNING, who died on March 22nd, aged 81 years, was educated at Edinburgh and became a Licentiate of the Royal College of Surgeons of Edinburgh in the year 1839 and took the degree of Doctor of Medicine in the University in 1846 In the year 1887 the degrees M.A. and LL.D. were conferred on him. Whilst he was at Edinburgh the use of chloroform was first introduced by Sir James Simpson and Gunning was present at the first public administration of the new anæsthetic. The period of his studentship was one of great theological perturbation, for at that time Dr. Chalmers was in the ascendant, and Gunning was one of his early supporters. He continued for the rest of his life to hold strong theological views and he never ceased to care for the welfare of the University and the city of Edinburgh. In the University of Edinburgh he founded the Victoria Jubilee prizes, 11 in number, of the value of £50 each, and he showed his interest in theological and political matters by erecting in St. Giles's Cathedral a brass plate on the site from which Jeanie Geddes is traditionally supposed to have thrown a stool at the priest as a protest against the form of prayer which was being used. More recently he originated the movement which led to the erection of a memorial to the Marquis of Argyle which has been recently put up in the same cathedral.

A great part of Dr. Gunning's life was spent in Brazil where he gained the confidence of the late Emperor, who created him a Grand Dignitary of the Order of the *Rose*. As one of the most distinguished Britons in Brazil Dr. Gunning naturally saw the more interesting of his countrymen who visited the empire, while his country house was practically open to any Englishman who wished to visit him. Dr. Gunning was twice married but leaves no family. During the last few years of his life he was completely blind, an affliction which he bore with exemplary patience. He was an extremely hospitable man, and his death will be felt by a large number of people who always found a welcome at his house, and an eager listener to any news which they might be able to bring, for nearly to the end of his long life he took the keenest pleasure in hearing about all passing events; and although he held strong views he was always ready to hear anything which could be urged against them.

WILLIAM CHAPMAN GRIGG, M.D. EDIN., M.R.C.P. LOND.

THE death occurred on March 12th, in the hospital at Wynberg, South Africa, of Dr. William Chapman Grigg. The cause of death was enteric fever. Dr. Grigg received his education at Birmingham, Bristol, King's College, London, and the University of Edinburgh. He also studied at Vienna. He became a Member of the Royal College of Surgeons of England in 1863 and a Licentiate of the Society of Apothecaries in 1864, graduated as M.D. at the University of Edinburgh in 1870, and in 1872 became a Member of the Royal College of Physicians of London. His practice was chiefly concerned with gynæcological and obstetric work, but he held the post of joint lecturer in forensic medicine at Westminster Hospital Medical School and was also physician to the Victoria Hospital for Children at Chelsea He was for some time obstetric physician to out-patients at Westminster Hospital and also held the posts of physician to in-patients at Queen's Charlotte's Lying-in Hospital and acting physician to the General Lying-in Hospital, York-road, Lambeth.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr J. O de Sande Saccadura Botte, Professor of Pharmacology and Dean of the Medical Faculty of the University of Coimbra.—Dr. Decès, Professor of Clinical Surgery in the Medical School of Rheims —Dr. G. Pacetti, *privat docent* of Neurology in the University of Rome —Dr. Eugen Boeckel, formerly a professor in the French Medical Faculty of Strasburg —Dr. Oscar Widman, Extraordinary Professor of Medical Pathology in Lemberg —Dr. Hoadley, Professor of Orthopædic Surgery in the Chicago College of Physicians and Surgeons —Dr. Hülsmann of Neheim who is believed to be the senior medical man in Germany. He was 92 years of age —Professor Otto Leichtenstern of Cologne whose name is known in connexion with researches on ankylostomiasis and who published a number of papers in association with Ziemssen, Gerhardt, and Nothnagel.—Dr. E. Lorenzo Holmes, Professor of Ophthalmology and Otology in the Rush Medical College, Chicago —Dr. J. Sroczynski, *privat-docent* of Ophthalmology in the University of Cracow.—Dr. A. von Tschurtschenthaler, formerly Professor of General Pathology in Innsbruck.—Professor von Mosengeil of Bonn.—Dr. Leroy, Professor of Medical Pathology in Lille.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held in March the following candidates passed in the subjects indicated:—

Surgery —W. T. C. Bennett (Section II), Sheffield; R. R. P. S. Bowker, Middlesex Hospital, H. N. Collier, Guy's Hospital; R. V. Cowey (Section I.) and W. K. S. Hay Coghlan, St. Mary's Hospital; R. C. Rumbelow, Middlesex Hospital, A. Y. St. Leger (Section II.), Cambridge and St Mary's Hospital, and T. Young (Sections I. and II), St Bartholomew's Hospital

Medicine —W D French (Section I), University College Hospital; H Jessop (Section I), Birmingham; W. T. Meagher, Cork; A. C. Oliver (Section II), Charing Cross Hospital, and J. R. Pooler (Section I), Birmingham.

Forensic Medicine —W D French, University College Hospital; H Jessop, Birmingham; W T. Meagher, Cork, J R Pooler, Birmingham, and H. F. Wallington, Manchester.

Midwifery —E I Lamport, Royal Free Hospital, C A. Lower, Guy's Hospital and Bristol, F A. Segreda, Guy's Hospital, and H P. Shanks, University College Hospital

The diploma of the Society was granted to the following candidates, entitling them to Practise Medicine, Surgery, and Midwifery.—W. F. C. Bennett and W K S Hay-Coghlan

DRAINAGE OF PLYMOUTH.—At the meeting of the Plymouth Borough Council held on March 12th it was decided to proceed with the construction of the main sea outfall in connexion with the drainage scheme of Plymouth. The cost was estimated at about £21,000.

THE POSITION OF THE MEDICAL OFFICER OF HEALTH TOWARDS HIS AUTHORITY —At a recent meeting of the Gloucester City Council Dr. J. Campbell stated that his report to the Local Government Board and to the local sanitary authority could not be altered by anybody. As a matter of courtesy he read it to the committee, but all the local authority had to decide was whether they would print it or not. It was subsequently stated that Dr. Campbell accepted suggestions made in committee on his report which was thoroughly considered before being ordered for printing. It was also urged that in the public interest the medical officer was protected from outside influence in the record of his opinions. A proposal to refer the minute back was withdrawn.

ROYAL INSTITUTION.—The Friday evening discourse at the Royal Institution on March 23rd was delivered by Sir Andrew Noble, the subject being Some Modern Explosives. The discourse was an elaborate exposition of the use of explosives in artillery. It was mentioned that cordite, the explosive at present employed, produced a muzzle velocity of the projectile nearly double that obtained with the powder used 40 or 50 years ago.

WEST CORNWALL WOMEN'S HOSPITAL, REDRUTH. —The annual meeting of governors and others interested in this institution was held on March 13th. The medical report stated that 127 women had been admitted during 1899 and 19 children since the opening of the children's ward last July. The financial statement showed that the income amounted to £410 and that a favourable balance of £25 remained.

HEALTH OF LAUNCESTON.—The annual report of the medical officer of health (Dr. C. G. Gibson) for 1899 states that there were 61 births, giving a rate of 14·02 per 1000; the deaths numbered 75, being a rate of 17·26 per 1000. The zymotic death-rate was 0·23 per 1000. Dr. Gibson draws attention to the astonishingly low birth-rate, and adds that a decrease of the population had to be recorded, instead of an increase as in former years. The medical officer of health further states that not a single case of typhoid fever had originated in Launceston since 1893. The new sewage works were now in good working order and giving satisfaction.

PRESENTATIONS TO MEDICAL MEN. — On March 15th Mr. Thomas Hamilton, M.B., C.M. Glasg., on the occasion of his leaving his native town, Dalry, Ayrshire, where he has successfully practised for some years, was presented by his numerous patients and friends, who appreciated his worth and medical skill, with a silver cigarette-case and a purse of sovereigns and a pearl brooch for Mrs. Hamilton.—Before leaving for the front, South Africa, Mr. William Wellington Lake, M.R.C.S. Eng., Surgeon-Lieutenant-Colonel, Militia Medical Staff Corps, was the recipient of a presentation from the officers f the Isolation Hospital, Guildford, and the clerk the Joint Hospital. He has discharged the duties of edical officer at the hospital for some years and e subscribers desired to give him some, though small, ngible token of their esteem and regard. The presentation s made privately, on their behalf, by the superintendent the hospital and consisted of a silver-mounted spirit binet.—On March 20th, at Pagani's Restaurant, Great tland-street, W., a presentation of a gold watch and in and silver cigarette-case was made to Dr. Major enwood, honorary secretary of the Brussels Medical duates' Association, by Dr. Danford Thomas, coroner Central London and Middlesex, in the name of the bers of that association, in recognition of Dr. Green-l's services Dr. Charles Burland, President of the iation, was in the chair, and many other members and ls were present. The inscription on the watch is as s: "Presented to Dr. M. Greenwood by members of .M.G.A., as a token of their high regard and a recognition of valuable services as Hon. Secretary — 1900."—At the annual dinner of the students of the n University College of Medicine, held on March 23rd, Hôtel Métropole, Newcastle, Dr. F. Page was pre- with a testimonial on his retirement from the post of to the Newcastle Infirmary. The testimonial con- f a five-light candelabra and six candlesticks to in Corinthian design, together with three silver lishes.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Lunacy Board in Scotland

the Government dealing with salaries, &c., in connexion acy Board in Scotland is likely to be keenly opposed. on is felt to the proposal to attach a salary or remune- ffice of chairman of the Board, which until now has been ointment.

The Sale of Undersized Fish.

ent has introduced again a Bill to prevent the sale of immature fish. The Bill follows very closely the recommendations the Select Committee which a few years ago inquired into the subject and obtained valuable evidence as to the wanton and wholesale destruction of undersized fish. The advocacy of the measure of Mr. Ritchie, President of the Board of Trade.

HOUSE OF COMMONS.

TUESDAY, MARCH 20TH.

The War Office and Civil Hospitals.

SIR EDGAR VINCENT asked the Under Secretary of State for War when it would be possible to give a decided answer to the offer made on Dec. 21st last by the Royal Devon and Exeter Hospital to take in 20 sick and wounded men of the Devon Regiment on their return from active service.—Mr. WYNDHAM: There has been some misapprehension on this point and I should like, if the House will allow me, to explain it rather fully. It was apprehended that the accommodation of the military hospitals might prove insufficient for the number of invalids arriving from South Africa. A circular was accordingly sent by the War Office to the various town and county hospitals to ascertain what number of beds could, if need should arise, be assigned to military patients. Our intention is to use these beds only as a reserve when the military hospitals are full. In many cases, including the Royal Devon and Exeter Hospital, we were met by the generous offer of a number of free beds. But the military hospitals are not yet full; only about 2000 invalids have so far arrived from South Africa and many of these have already been sent on sick furlough, so that it is impossible to say when or where recourse must be had to civil hospitals. There is, however, no necessity for keeping beds vacant in any civil hospital, since we propose to give 10 days' or a fortnight's notice in every case.

THURSDAY, MARCH 22ND.

The Infliction of Corporal Punishment in Prisons.

Sir CHARLES CAMERON asked the Home Secretary whether there were any and if so what regulations providing for the special medical examination of persons sentenced to flogging as to their fitness to undergo such punishment before it was inflicted; whether the gaol surgeon or any other officer had power to suspend or dispense with such a sentence, if in his opinion the constitution of the person sentenced to flogging was not fit to bear it; and what precautions were taken and in whom was the duty vested to ascertain whether juvenile offenders sentenced to whipping were able to bear it without danger to health.—Sir MATTHEW WHITE RIDLEY: Rule 87 (Local Prisons Rules) directs that corporal punishment shall not be inflicted unless the medical officer has certified that the prisoner is in a fit condition to undergo the punishment. Rule 182 also directs that before a prisoner is subjected to corporal punishment the medical officer shall examine him and certify whether or not he is fit for the punishment. Rule 182 further directs that the instructions of the medical officer for preventing injury to health by corporal punishment shall be obeyed. These rules apply also to juvenile offenders sentenced to whipping when such whipping is carried out by the prison authorities. Whippings administered by the police are subject to similar police regulations. The rules for convict prisons contain similar provisions to those in force in local prisons with respect to convicts ordered to be flogged for prison offences.

The Boots of the Soldiers in South Africa.

Mr. POWELL WILLIAMS, answering a question on this subject addressed to him by General RUSSELL, said: The foreign service hand-sewn, steel-billed boots and the hob-nailed boots received from India and Egypt have proved satisfactory for infantry, but Lord Roberts has complained of the home pattern clump-soled boot. We have sent out in round numbers 103,000 home and 132,000 foreign pattern, and more will be sent as fast as they can be procured. The hand sewn boot trade seems to be an expiring industry, and we are endeavouring to obtain a pattern of machine sewn boot which shall be equally suitable for home or foreign wear.

FRIDAY, MARCH 23RD.

The Petroleum Question.

Mr. CHANNING asked the Home Secretary whether he was aware that the Public Control Committee of the London County Council had stated in their report that the decrease of fatal lamp accidents in London from 34 in 1898 to 23 in 1899 might probably be traced to the increased quantity of high-flash Russian oil now being imported into London and to the decreased use of low flash American oils; and whether he would bring in a Bill to raise the flash-point in accordance with the public opinion thus indicated.—Sir MATTHEW WHITE RIDLEY The report referred to has been brought to my notice, but its contents hardly appear to afford sufficient data to warrant the conclusions suggested in the question. As to legislation, I must repeat that I can give no undertaking.

The High Death rate in Dublin: Suggested Explanation.

Mr. T. M. HEALY asked the President of the Board of Trade if his attention had been called to the published report of Professor E Reynolds, of Trinity College, Dublin, warning the public of his discovery that the Dublin Gas Company, without notice to the citizens or the corporation, had turned 17 per cent. of carbon monoxide into their mains; did the Board of Trade receive any notice of this intermixture of water-gas with coal-gas in Dublin; was he aware that water gas was the most deadly gaseous poison known, was absolutely fatal to animal life, and that its use as an illuminant had been made illegal in many American States, was he aware that leakages from the Dublin mains were constant and that since the introduction of water-gas the death rate amongst the population had risen so enormously that the Lord Lieutenant had appointed a commission to investigate the cause; had he any information to show whether the poison from water-gas was cumulative in the human system; and whether any remedy known to science existed for even cases of partial poisoning, and would the Government take any steps to protect the public from the admixture of this product with ordinary coal-gas.—Mr. RITCHIE: I have not seen the published report to which the hon.

and learned Member refers, but I understand that Professor Reynolds in a lecture at Trinity College recently made some observations as to the increased proportion of carbonic oxide in the gas supplied in Dublin due to the admixture of carburetted water-gas with coal gas. The Board of Trade received no notice of the intention of the gas company to make any alteration in the nature of the gas nor are the company required to give such notice, but they have now informed the Board that the plans of the necessary works were submitted to the corporation and their purpose explained.' I am not aware that the use of water-gas has been made illegal in any American State, but from the report issued last year of a Home Office Departmental Committee which inquired into the question of the supply of water-gas it appears that in the United States carburetted water gas is very largely used and formed in 1896 about 70 per cent. of the total gas-supply. The hon and learned Member will by a perusal of the report obtain much information with reference to this interesting subject which it is impossible to summarise in an answer to his question. The Local Government Board for Ireland inform me that they are not aware whether the high death rate is in any degree attributable to the alleged leakage of gas. The commission appointed by the Lord Lieutenant has directed its inquiries into the general causes of the death rate, and pending the report of the commission that Board can express no definite opinion on the point.

MONDAY, MARCH 26TH.

A Guy's Hospital Case.

MR. **CHANNING** asked the Home Secretary whether his attention had been called to the evidence given at a coroner's inquest at Bermondsey on Friday, March 15th, on an infant named Mabel Blanch, that the child was seen and prescribed for by an unqualified student at Guy's Hospital, and subsequently died; and whether he would make a representation to the authorities of Guy's Hospital that effect should forthwith be given to the rider of the jury that patients should in every case be examined by a qualified medical man and a record kept of the prescriptions.—Sir **MATTHEW WHITE RIDLEY**: I find that the facts are as stated in the question, except that the jury do not appear to have believed that any prescription was given. I am assured by the authorities of Guy's Hospital that it is entirely against the regulations for unqualified students to treat patients on their own responsibility, and that on the day following the child's death the case was brought before them and the student dealt with by them

London Telegraphists and Medical Attendance.

Mr. **M'GHEE** asked the Secretary to the Treasury, as representing the Postmaster General, whether London telegraph clerks were entitled to free medical attendance, and whether the official doctors' officers visit patients who could not leave their homes; and whether the Postmaster-General would take steps to make adequate provision for giving the London telegraphists free medical attendance, in accordance with the statement made in the Parliamentary Return issued on the motion of the member for the Blackfriars Division of Glasgow in 1898.—Mr. **HANBURY**: There are no persons called telegraph clerks in London The London telegraphists whose salaries are not over £160 a year are allowed free medical attendance at their offices or at their homes provided that the homes are within the prescribed limit of three miles from the head office of the district in which they are employed If they reside beyond this limit they are entitled to receive advice and medicine on application at the surgery of the medical officer.

WEDNESDAY, MARCH 28TH.

Corporal Punishment.

At this sitting the House debated a Bill to consolidate the law with regard to corporal punishment and to give Her Majesty's judges and chairmen of Quarter Sessions power to order it in certain cases of violence towards women and children The **HOME SECRETARY** and other prominent Members opposed the Bill as a retrograde step, and the House rejected it by 195 votes to 72

THE MIDWIVES BILL.

PASSAGE THROUGH THE STANDING COMMITTEE.

The Midwives Bill has passed through the Standing Committee of the House of Commons on Law and now awaits the report stage. Its position, therefore, is one of great advantage, and, indeed, the medical profession may reckon on the Bill becoming an Act before the close of the session The proceedings in the Standing Committee occupied two days, and while they were marked by great zeal and activity on the part of the promoters and their friends, the same cannot be said of the critics of the Bill or of those to whom they naturally looked for assistance and encouragement The small space in the rear of the hall allocated to the public was crowded with ladies and gentlemen prominently identified with the movement for this class of legislation and from time to time members of the Committee interested in the passage of the Bill came to them, if not for instructions, at any rate for aid in the conduct of their case. No such aid appeared to be available for the other side On the Committee itself there were few medical members, only Dr Ambrose and Sir George Pilkington The latter attended the first day and moved a number or amendments, but the former put in an appearance on neither occasion. Apart from Sir George Pilkington most of the criticism of the Bill was done by Mr. Lloyd George and Mr. T P O'Connor, who showed a very keen and intelligent appreciation of its tendencies.

PROCEEDINGS IN THE HOUSE.

THURSDAY, MARCH 22ND.

After midnight at this sitting the House went into Committee "to consider of authorising the payment out of moneys to be provided by Parliament of such expenses as the Treasury may certify to have been necessarily incurred by the General Medical Council under any Act of the present session to secure the better training of midwives and to regulate their practice"

Mr. T. M. **HEALY** took exception to the subject being discussed now when the Bill itself had not been considered by the Standing Committee. He thought it was a strong thing to assume that the Standing Committee would pass the Bill and pass it in a shape which would require a money vote for the General Medical Council It would, in his opinion, be much more satisfactory to wait and see what was done with the Bill in the Standing Committee

Sir **JOHN GORST**, who had charge of the business, said this was merely a formal proceeding rendered necessary by the fact of money being required to carry out the Act. The Bill in question was a measure about which there had been a great deal of negotiation and an agreement had been come to that certain small expenditure which would be borne by the General Medical Council should be met by the Government. The private Members who promoted the Bill could not possibly move such a resolution as this, and he as a representative of the Government was moving it in order to carry out the agreement come to. It would be for the House to discuss the proposal in Committee and afterwards on report.

Mr. **HEALY** said that while he did not wish to interfere with any arrangement come to he felt that any action taken now would prejudge the case. In the Standing Committee it might be said that the House had already voted, and voted cheerfully, this money.

Mr. **DALY** expressed the opinion that it would be a bad precedent.

The **CHAIRMAN** asked the hon. Member whether he objected to the resolution being taken.

Mr. **DALY** replied in the affirmative.

According to the rules of the House, it being after midnight and objection being taken, the business stood adjourned.

PROCEEDINGS IN THE STANDING COMMITTEE.

FRIDAY, MARCH 23RD.

The Standing Committee on Law of the House of Commons met to-day, with Mr. **LAWRENCE HARDY** in the chair, and proceeded with the consideration of the Bill

Clause 1 as printed said "this Act may for all purposes be cited as the Midwives Act, 1900. *It shall come into force on the first day of April, 1901*"

Mr T P. **O'CONNOR**, on behalf of Mr. **LLOYD-GEORGE**, moved to leave out "midwives" and insert "midwifery nurses." The members of the Committee, he said, were aware that the main objection of the medical profession, or at any rate of the great majority of that profession, was that this measure would transform the midwife and give her all the privileges of a medical man, and the purpose of this amendment was to make it clear that midwives were nurses and not medical practitioners.

Mr **HEYWOOD JOHNSTONE**, the Member in charge of the Bill, said that if he and his friends were to accept this amendment the whole character of the measure would be altered He would not occupy the time of the Committee with argument, but simply say that the term "midwife" was well understood and that in his opinion the fears of the hon. Members were groundless

Dr. **COMMINS**, supporting the amendment, said that in the public mind there would be confusion as between the medical man qualified after long study to practise midwifery, as well as medicine and surgery, and the midwife certified under this Act. In these circumstances he regarded the amendment as absolutely necessary.

Mr. **HAZELL** submitted that the danger apprehended by the movers of the amendment was sufficiently safeguarded by Section 4, where the Central Midwives Board was directed to make rules regulating, supervising, and restricting within due limits the practice of midwives.

Mr. **LLOYD-GEORGE** said that the Bill in its present shape made a serious alteration in the law The state of the law was that no unqualified practitioner could practise midwifery Even the qualified practitioner could not employ an unqualified doctor, no matter how great the experience of the latter in midwifery cases, to assist him in his work If the qualified practitioner did so he was liable to be dismissed from the profession for infamous conduct in a professional respect. Such cases had occurred in the mining districts of Wales and the medical men concerned had been removed from the Medical Register. According to this Bill they denied to the unqualified doctor, no matter how great his experience, what they allowed to a midwife with two or three months' training That was surely a mistake. Indeed, he thought it an absurdity that midwives should be allowed to act as responsible members of the medical profession, and he considered the committee would do well to confine the operations of these women to midwifery nursing. If this Bill were passed then the women in the mining districts of Wales who were now attended by qualified medical men would be attended by midwives registered and certified under this Bill. He thought that very unfair, and he should like to know whether the fashionable ladies who promoted this Bill would like to have the experiment tried upon them. For himself he objected to the experiment being tried upon the humbler classes of the community.

Sir **GEORGE PILKINGTON** thought it was the duty of Parliament to guard the poorer portion of the community against any possibility of misunderstanding in these matters. He thought, too, that the different classes of nurses should be distinguished.

Mr **VICARY GIBBS** said that this was a Bill dealing with midwives and he could not conceive why they should call the people concerned by any other name than midwives. Manifestly those who moved this amendment attacked the principle of the Bill

Mr **GEORGE HARWOOD** took the view that as they were creating a new class of persons it was perfectly right and logical that they should give them a new name The name "midwife" suggested a person not very capable, whereas these persons were to be properly trained, and he thought in their own interests they should have a name making it clear that they were duly qualified for their work.

Mr. **HEYWOOD JOHNSTONE** denied that the Bill created a new class of persons It simply provided that the existing class known as midwives should have some training and show some evidence of competence before carrying on the profession He thought the report of the Select Committee showed that medical men had nothing whatever to fear from the competition of these women Trained women knew when they needed the assistance of the medical man and would send for him, and by having trained women, and trained women only, much suffering would be spared

Sir George Pilkington said that the medical profession did not for ne moment fear competition. What they did fear was that poor omen would not receive proper skilled attention in their time of ouble.

The amendment was then put to the Committee and rejected by 0 tes to 5.

lause 2 in the Bill was in the following terms, viz.:—

—(1) From and after Jan. 1st, 1902, no woman shall be entitled to or use the name or title of midwife (either alone or in combination any other word or words), or any name, title, addition, or description implying that she is certified under this Act, or is qualified to act as a midwife, unless she be certified under this Act.

(2) Any woman who, after Jan. 1st, 1902, not being certified under this Act, shall take or use the name of midwife or any other such name, title, addition, or description as aforesaid, or shall habitually and for gain attend women in childbirth, shall be liable on summary conviction to a fine not exceeding £5.

(3) No woman shall be certified under this Act until she has complied with the rules and regulations to be laid down in pursuance of the terms of this Act.

(4) No woman certified under this Act shall employ as her substitute, or assistant, an uncertified person.

(5) The certificate under this Act shall not confer upon any woman any right or title to be registered under the Medical Acts or to assume any name, title, or designation implying that she is by law recognised as a medical practitioner, or that she is qualified to grant any medical certificate or any certificate of death or of stillbirth, or to attend cases of abnormal labour, or of disease of, or danger to, the mother or the child.

On the motion of Colonel Milward it was agreed to alter the date from Jan. 1st, 1902, to Jan. 1st, 1903.

Colonel Milward moved to amend the second sub-section so as to read: any woman who, &c., shall take or use the name of midwife or any other such name, title, addition, or description as aforesaid *and* shall habitually and for gain, &c. He said he was not prepared to go so far as to say that no person except a registered midwife should be called in, and the object of his amendment was to prevent the entire wiping out of poor women who in rural districts gave assistance to lying-in women.

Mr. Heywood Johnstone said he had great sympathy with the object of his hon. friend which he understood to be to protect the rights of poorer women practising in villages to attend upon their neighbours at necessary times, and if any amendment could be suggested which would make that absolutely clear it would have from the promoters of the Bill their most anxious and most benevolent consideration. Women engaged at the present time in practice were protected by Clause 3 which dealt with persons in *bonâ-fide* practice and bearing satisfactory character.

Mr. Helder said that it was obvious that the clause in its present form would cut out a large number of persons who at the present moment were doing good work and therefore he should like to see it amended.

Mr. Vicary Gibbs expressed the view that this amendment if passed would knock the bottom out of the Bill. It would destroy what the strongest opponents of the measure recognise as its chief merit. Everybody desired that the poor should be protected from incompetent quacks and whatever might be the wishes of the mover of the amendment the effect of what he proposed would be to leave them at the mercy of these quacks. Therefore he hoped the amendment would not be pressed.

Colonel Milward explained that he considered the Bill too drastic in its present shape, but as the hon. Member in charge of the Bill had kindly said he would accept an amendment to carry out what he had in view——

Mr. Heywood Johnstone: Benevolently consider.

Colonel Milward: Benevolently consider; quite so—he was willing to withdraw the amendment.

Mr. T. P. O'Connor said that his position was not to weaken the qualifications of midwives but to strengthen them. He thought it could be shown that if this amendment were carried an unqualified woman could very often practise midwifery if only she avoided calling herself a midwife, and that surely was a fatal objection to the amendment. Yet at the same time the promoters of the Bill must know that if the measure passed in its present form a large number of women who had done this duty as an act of neighbourliness and sometimes perhaps as a small addition to their means would be excluded. He would ask his hon. friend (Mr. Heywood Johnstone) to consider this and endeavour to meet the case. It was demanded that lying-in women should be attended only by a skilled midwife. If they had battalions of skilled midwives ready to spread themselves through all the villages of the country he could understand the Bill, but such was far from being the case. There must be a very considerable interval before they could have this strength of skilled midwives, and he thought his hon. friend should come forward with some practical proposal and not be content with benevolent consideration.

The amendment was then withdrawn.

Mr. Lloyd-George moved to substitute "authorised" for "qualified" in sub-section 5 of the clause.

Sir George Pilkington said that the word "qualified" was calculated to deceive. It applied to a degree in a medical school and he did not think it should be used in connexion with this Bill at all.

The Committee agreed to the proposed alteration.

Colonel Milward moved to leave out all after the word "still-birth" in sub-section five and to insert "and she shall apply for qualified medical assistance in every case which presents abnormality, danger or disease on the part of the mother or of the new-born child."

Mr. Heywood Johnstone said he was afraid that again he could not accede to the wishes of his hon. friend. If this matter was to be provided for at all it should be provided for in the rules made for the guidance of midwives by the Central Midwives Board. He strongly objected to placing upon one particular class of persons in the kingdom a statutory responsibility to send for medical assistance at this particular juncture. If these women were properly trained, as this Bill sought to ensure, then they would know when to send for medical assistance. But why should they put upon them by statute an obligation which they put upon no one else in the community?

The amendment was withdrawn without further debate.

Mr. Lloyd-George moved to insert at the end of the clause the following words, viz.: 'And if any woman certificated under this Act shall do or purport to do anything which by this sub-section it is declared that her certificate does not confer upon her a right or title to do, she shall be liable on summary conviction to a fine not exceeding £5."

Mr. Arthur Elliot said it appeared somewhat hard that a woman should be penalised in the manner proposed if when trouble suddenly arose she endeavoured to the best of her ability to deal with it.

Mr. Vicary Gibbs said it might be necessary at a moment's notice for a midwife to do something in order to save life which would not be her duty in ordinary circumstances. Did the opponents of the Bill mean that she was to leave her patient to die, though measures for her preservation were quite within her power?

Mr. Lloyd-George said it appeared to him that the speeches to which the Committee had just listened indicated what was the real object of the promoters of the Bill. It was intended to set up a perfectly new profession. The Bill proposed to register women who were really nurses and it was obvious that the promoters contemplate that these women should be a separate profession which was not recognised nominally by the Bill. That went to the very root of his objection to the Bill and he thought the promoters had given away their case. He would press the matter now and if he were defeated he would press it again in the House of Commons.

Mr. Parker Smith thought the hon. Member hardly realised the meaning of his amendment. The amendment proposed that if a woman did anything which her certificate did not empower her to do she should be liable to a penalty. She might go to a confinement which was expected to be normal. It turned out to be abnormal and she sent for a doctor. Before the doctor arrived it became absolutely necessary that she should do something and if she did anything she became liable to this penalty. This happened if she were an authorised person. But if she were an unauthorised and uncertificated person she was liable to no such penalty and might do what she liked.

Mr. Lloyd-George said that the point was whether the woman represented that her certificate authorised her to do the thing. If she represented that she was authorised to do the thing when such was contrary to the fact then he certainly thought she should be punished.

Mr. Atherley-Jones said this amendment was obviously intended to make as difficult as possible the benefits aimed at under this Bill. It was an amendment framed in the interests of the medical profession and he hoped the Committee would not accept it.

Mr. Lloyd-George asked whether the promoters of the Bill would accept an amendment which simply covered false representation.

Mr. Vicary Gibbs intimated that he for one would accept such an amendment.

Mr. T. P. O'Connor said he felt there was great force in the case presented by Mr. Parker Smith, but while that was so he thought there was a matter here which the promoters of the Bill ought to consider. The objection of the opponents of the measure was that these midwives were not to be midwives and nurses, but medical practitioners with all the rights of medical practitioners. It was quite true that a woman was not, under her certificate, authorised to attend a case of abnormal labour or of disease of, or danger to, the mother or the child, but the illustration given by Mr. Parker Smith showed that though she was not authorised the woman might do it. Where, then, was the protection? There ought surely to be some safeguard. At the very least it ought to be put upon the midwife to prove that there was danger to mother or child when she interfered. If the promoters did not put in some proviso then they proved the whole case of the opponents that these midwives were not merely doing ordinary midwife and nursing work, but were assuming all the privileges and duties of medical practitioners.

The Solicitor-General (Sir Robert Finlay) said that while he understood what the mover of the amendment meant he did not think that the words he had proposed brought out his meaning and he suggested that in the meantime the amendment should be withdrawn, leaving the matter to be dealt with in the House on the Report stage of the Bill.

Mr. T. P. O'Connor thought the Committee should have a declaration from the promoters of the Bill as to what they were prepared to do in this connexion.

Mr. Heywood Johnstone said that his view was that the Committee was now in a position to take a division upon the amendment unless it were withdrawn. The amendment referred to a woman certificated under the Act and Clause 4 provided for the making of rules "regulating, supervising, and restricting within due limits the practice of midwives." A rule made under this clause would, he thought, amply meet all the difficulties and anxieties raised by hon. Members.

Mr. Parker Smith said he certainly objected to a midwife holding out that she was capable of dealing with abnormal cases. He should like to know whether under the general law a woman dealing with dangerous cases would be in the same position whether licensed or unlicensed, assuming she could not plead emergency and assuming she had had ample notice and did not send for a doctor. He should like to ask the Solicitor-General whether it was necessary to have a special penalty for such a case.

The Solicitor-General replied that he did not think the existing law would deal with this case unless provision were made for it. This matter, however, might be provided for in a rule for the practice of midwives. A rule in stringent terms might be framed providing that any registered midwife who held herself out as qualified to do that which she was not authorised to do, might have her certificate withdrawn. Perhaps the promoters of the Bill would consider the point.

At the request of Mr. Lloyd-George the amendment was withdrawn.

The Committee then proceeded to the consideration of Clause 3, the terms of which were as follows, viz.:—

3. Any woman who, within two years from the date of this Act coming into operation, claims to be certified under this Act shall be so certified provided she holds a certificate in midwifery from the Royal College of Physicians of Ireland or from the Obstetrical Society of London, or such other certificate as may be approved by the Central Midwives Board, or produces evidence satisfactory to the Board that at the passing of this Act she has been in *bonâ-fide* practice as a midwife and that she bears a good character.

Sir George Pilkington moved to insert after "provided" the words "that she bears a good character and that."

Mr. Heywood Johnstone hoped the hon. Member would not press this amendment because it really cast a slur upon the two bodies whose certificates under the Bill were to be accepted as sufficient for the qualification of existing midwives

The amendment was not pressed

Sir George Pilkington moved to leave out the reference to the Royal College of Physicians of Ireland and the Obstetrical Society of London and make the clause simply run: Provided she holds a certificate in midwifery approved by the Central Midwives Board &c

Mr Heywood Johnstone said that the certificate of the Obstetrical Society would cease to exist after the passing of this legislation Since 1872 the society had been engaged in the voluntary work of examining women who wished some certificate or qualification and he thought it would be a somewhat ungracious thing to withhold recognition of this work

The amendment was rejected without a division

The Committee then took up Clause 4 viz —

4 On the passing of this Act the President of the General Medical Council shall take steps to secure the formation of a Central Midwives Board which shall consist of—

(1) Four registered medical practitioners, one to be appointed by the Royal College of Physicians of London, one by the Royal College of Surgeons of England, one by the Society of Apothecaries and one by the Incorporated Midwives Institute,

(2) Two persons (one of whom shall be a woman) to be appointed for terms of three years by the Lord President of the Council; and

(3) One person to be appointed for a term of three years by the Association of County Councils.

After two years from the date of this Act coming into operation the members appointed under subsection (1) shall retire but shall be eligible for re-appointment annually Any vacancy occurring by resignation or death shall be filled up in the case of a member appointed under subsections (1) and (3) by the body which appointed him and in the case of a member appointed under subsection (2) by the Lord President of the Council

The duties of the Board shall be as follows:—

I To frame rules subject to the approval of the General Medical Council

(a) regulating the issue of certificates and the conditions of admission to the roll,

(b) regulating the course of training and the conduct of examinations

(c) regulating the admission to the roll of women already in practice as midwives at the passing of this Act,

(d) regulating, supervising and restricting within due limits the practice of midwives,

(e) deciding the conditions under which midwives may be suspended from practice;

II To appoint examiners,

III To decide upon the places where, and the times when examinations shall be held;

IV To publish annually a roll of midwives who have been duly certified under the Act

V To decide upon the removal from the roll of the name of any midwife for disobeying the rules and regulations from time to time laid down under this Act by the Central Midwives Board or for other misconduct, and also to decide upon the restoration to the roll of the name of any midwife so removed;

VI To issue certificates

And generally to do any other act or duty which may be necessary for the due and proper carrying out of the provisions of this Act

On the motion of Sir George Pilkington it was agreed to strike out the words the President of in the first sentence of the clause

Sir George Pilkington moved to make the first subsection read "Four registered medical practitioners to be appointed by the General Medical Council as follows one practising in the London and South Eastern Registration Divisions, one practising in the South Western West Midland or Welsh Registration Divisions one practising in the Eastern North Midland or South Midland Registration Divisions and one practising in the Yorkshire or Northern Registration Divisions, as from time to time defined by the Registrar General Sir George Pilkington explained that the object of his amendment was to secure for the Central Midwives Board thoroughly representative general practitioners rather than men who occupy distinguished positions as consultants and specialists believing as he did that the former were the better fitted for the work to be done

Mr Heywood Johnstone said he saw nothing in this amendment which would favour the rank and file of the medical profession

The amendment was withdrawn without further discussion

Mr Atherley Jones moved the omission of the words subject to the approval of the General Medical Council No doubt he said there was great opposition to this measure by a considerable number of practising medical men and the reason for that opposition was founded upon the idea that by establishing under the sanction of Parliament a class of certificated midwives the humbler classes of the community would avail themselves of these registered midwives in preference to the ordinary medical practitioner and therefore the object of a very large section of medical men was to try to impose as many restrictions and difficulties——

Several Members No No

Mr Atherley Jones I have had many communications with medical men in many parts of the country—to try to impose as many restrictions and difficulties as possible in the way The Bill provided for the formation of a Central Midwives Board and the constitution of that Board provided that there should be four registered medical practitioners two persons who would probably be medical men appointed by the Lord President of the Council, and one person who might be a medical man appointed by the Association of County Councils It seemed to him that such a body ought to be perfectly fitted for the purpose of framing rules without the assistance of the General Medical Council, and he could not see why there should be a sort of *imperium in imperio* in such a matter It had been pointed out to him that by making these rules subject to the General Medical Council they might have possibly vexatious and at any rate restrictive rules and regulations which would tend much to discourage the employment of midwives There could not be the slightest doubt that to the working classes of this country it was a great boon to be able to get that cheap and effective medical assistance which was provided by a midwife in contradistinction to a medical man

Mr Heywood Johnstone said that the promoters could not accept this amendment All throughout it had been a condition that any rules should be made subject to the approval of the General Medical Council After the assistance the promoters had received from the General Medical Council they could not in honour throw them over in the manner proposed

Sir George Pilkington said he felt sure that the General Medical Council would be able to give excellent advice to the proposed board He greatly regretted that the hon Member (Mr Atherley Jones) had found it necessary to impute to the medical profession so low a motive in this matter as to oust the midwife The medical profession were only anxious that poor women should have skilled attendance the value of which their education and training in medicine, surgery and midwifery enabled them to appreciate

Mr Atherley Jones said that after what had fallen from the Member in charge of the Bill he would not press the amendment

The amendment was accordingly withdrawn

Mr Lloyd-George moved to insert in the subsection dealing with removal from the roll these words "And so that for the purposes of this Act the omission to summon a registered medical practitioner in a case of abnormal labour shall be deemed to be misconduct"

The hon Member said that his object in moving this amendment was to have it made clear that it was the duty of midwives to send for a medical man in abnormal cases and that if they failed to do so it was at their own peril

Mr Heywood Johnstone said it appeared to him that it would be an unfortunate thing to fix a statutory responsibility upon midwives which could he believed, very easily be fixed by rule The rules to be framed would naturally specify the occasions upon which the midwife was to send for medical assistance

Mr Lloyd-George said that in this matter he was rather inclined to agree with the hon Member and he would withdraw his amendment

Sir George Pilkington moved to insert the following additional subsection, viz: "VII At the discretion of the Board to inspect or cause to be inspected from time to time any premises wherein any woman receives or proposes to receive as a midwife a pregnant or lying in woman, and if such premises shall, in the opinion of the board be fit for the reception of a pregnant or lying in woman the Board shall issue a certificate to that effect upon payment by the midwife of such fee as may be fixed by the Board, and shall enter such premises upon a register to be kept by the Board

Mr Parker Smith said he scarcely saw how this would fit in with the other functions of the Board

Colonel Milward suggested that the power might be given to the local supervising authority

Sir Francis Powell, supporting this suggestion said he did not see how the Central Board in London could discharge this duty

Mr Warr appealed to the promoters of the Bill to give this important matter their serious consideration

Mr Heywood Johnstone replied that the matter would most certainly be considered by them and they would be happy to receive any suggestions

The Solicitor General said it might be well to consult the Local Government Board

Meantime the amendment was withdrawn

Clause 5 was passed by the Committee in the following amended form viz:—

5 There shall be payable by every woman presenting herself for examination or certificate such fee as the Central Midwives Board may with the approval of the General Medical Council from time to time determine, such fee not to exceed the sum of one guinea All such fees paid by existing midwives and by candidates for examination shall be paid to the Central Midwives Board The said Board shall devote such fees to the payment of expenses connected with the examination and certificate and to the general expenses of the Board The Board shall as soon as practicable after the 31st day of December in each year publish a financial statement made up to that date and certified by a chartered accountant as correct showing the receipts and expenditure including liabilities, of the Board during the year The Board may apportion between the councils of the several counties and county boroughs any balance against the Board shown in the financial statement in proportion to the number of midwives licensed during the year to practise in those areas respectively, and may recover from the councils the sum so apportioned

Mr Lloyd George moved to add to the clause the words "The general expenses of the Board shall include the payment to the members thereof of remuneration for their services and reasonable travelling expenses upon such a scale as may be approved by the Treasury"

The Solicitor General intimated that the Treasury objected to this addition.

Mr Lloyd-George said that at present there was no machinery at all in the Bill to fix the expenses.

Mr Heywood Johnstone said the intention of the promoters was that the Board should be an unpaid board The promoters had taken the matter carefully into consideration They were told that it would be more acceptable to the profession if they had an opportunity of doing honourable and valuable service of this sort without any possibility of its being thrown in their teeth that they desired to be paid for it

The amendment was rejected by 20 votes to 4

Clause 6 giving power to county councils to contribute towards making good any deficiency in the funds of the Board was postponed

Clauses 7 and 8, dealing respectively with the midwives roll and the appointment of a secretary to the Board were passed without debate

The Committee then proceeded to the consideration of Clause 9 which ran as follows in the Bill as printed, viz:—

9 Every county council or council of a county borough throughout England and Wales shall, on the date of this Act coming into operation constitute the local supervising authority over midwives within the area of the said county or county borough. It shall be the duty of the local supervising authority—

1 To issue licences.

2. To exercise general supervision over all midwives practising within the prescribed area in accordance with the rules to be laid down under the provisions of this Act

3. To investigate charges of malpractice negligence or misconduct on the part of any midwife practising within the district and should

a *primâ facie* case be established to report the same to the Central Midwives Board.

4. To suspend any midwife from practice, in accordance with the rules to be laid down by the Central Midwives Board and approved of by the General Medical Council, if such suspension appears necessary to prevent the spread of infection.

5. To report at once to the said Board the name of any midwife practising in the district convicted of a misdemeanour or felony.

6. During the month of January of each year to supply the secretary of the Central Midwives Board with the names and addresses of all midwives practising in the district and to keep a current copy of the midwives roll accessible at all reasonable times for public inspection.

7. To report at once to the Central Midwives Board the death of any midwife or any change in the name or address of any midwife in the district so that the necessary alteration may be made in the roll.

Mr. Lloyd George moved to strike out of the first sentence the word "constitute" and insert "appoint a committee of not fewer than three registered medical practitioners, not teachers or examiners of midwives, as." He thought it was obvious that for this purpose they should have a medical committee.

Mr. Atherley-Jones said this amendment clearly demonstrated what he had said, that there was an attempt on the part of a few members of this Committee to so restrict the operation of the Act as to make midwives unable to really serve a useful purpose. This amendment was designed to put the midwives under the control of a rival body of persons in the same county. He said so advisedly. He had received numerous representations by medical men that the result of passing this Bill would be to cause midwives to be employed in preference to medical men. He hoped that the promoters of the Bill would resist this amendment. He really felt, in spite of what had been said by Sir George Pilkington, that he (Mr. Atherley-Jones) was amply justified in the observations he made as to the considerations which operated in this matter.

Colonel Milward said he should be prepared to support a proposal that one member of the authority should be a medical man.

Mr. Parker Smith thought they might leave the matter to the discretion of the county council.

Sir George Pilkington said he felt sure the county council would not leave out of account medical representation.

Mr. Heywood Johnstone thought they could trust to the good sense and practical working of the county council. He could not associate himself with the somewhat ungenerous remarks of the hon. Member (Mr. Atherley-Jones) about the conduct of the medical profession. While honestly putting forward their views the medical profession had given the promoters of the Bill the greatest possible assistance.

Mr. Vicary Gibbs said he had conversed with many medical men on the subject and he had not found amongst them any hostility to the Bill. As for himself, he was supporting the Bill because he thought it was in the interests of the very poor and not with the slightest feeling of hostility to the medical profession.

Several Members expressed difficulty about the meaning of the word "*constitute*" in the clause.

The Chairman suggested that it would facilitate debate if he put from the chair the question that "constitute" stand part of the clause.

This question was put and the Committee decided that the word should be removed from the clause.

The Solicitor-General suggested that the best way of meeting the opinion of the Committee would be to say that the county council should be the authority and to insert words to the effect that the county council might appoint a committee not necessarily consisting of members of the county council.

This suggestion commended itself to the Committee and was adopted, Mr. Lloyd-George's amendment being withdrawn.

A proposal by Colonel Milward for the framing of a scale of charges for midwives was not passed.

The Committee then adjourned until Tuesday.

Proceedings in the House.

Friday, March 23rd.

At ten minutes before midnight the House again went into committee on the resolution for making good to the General Medical Council any expenses necessarily incurred under the proposed legislation. Mr. Daly expressed objection to the resolution being passed and in Parliamentary phrase "talked it out"—that is to say, continued speaking until midnight, when by the rules of the House the debate stood adjourned.

Proceedings in the Standing Committee.

Tuesday, March 27th.

The Standing Committee held another meeting to-day, with Mr. Lawrence Hardy in the chair, and completed the consideration of the Bill. There was some delay at the start owing to the absence of the necessary quorum, but once the 20 members had been got together the proceedings only occupied three-quarters of an hour.

On Clause 9 dealing with the local supervision of midwives

Mr. Heywood Johnstone explained that as the clause stood it proposed that it shall be the duty of the local supervising authority during the month of January of each year to supply the Secretary of the Central Midwives Board with the names and addresses of all midwives practising in the district. He moved to alter the clause so as to provide that the licence shall be taken out in the month of January each year and that the names and addresses shall be sent in during the following month—namely, February.

The clause was amended in this sense.

Mr. Warr moved to insert words providing that "it shall be lawful for the local supervising authority to make from time to time any such order as to them seems fit for prescribing and regulating the remuneration of midwives practising in the district."

Sir Frederick Godson said he thought the remuneration of midwives should be left to the operation of the laws of supply and demand and not fixed by the local supervising authority.

Mr. Bonsor spoke of the proposal as a retrograde step, as almost going back to the days when the price of bread was regulated by some constituted authority. He felt sure that in the towns competition would practically settle the scale of charges, while in country villages there would always be someone who would see that the people were not overcharged.

Sir Frederick Godson said that only on Saturday he was speaking to one of the medical men in his district who was a very strong supporter of the Bill generally, but who was certain that in the opinion of the medical profession in the district such a clause as this would do more harm than good.

Mr. Vicary Gibbs condemned the proposal as an extension of a mischievous principle.

Colonel Milward thought it was absolutely necessary that in the small villages poor women should have some protection against extortionate charges.

Mr. Hazell hoped the amendment would not be pressed. He feared that in the case of a supervising authority whose opinion was that this work should be done, not by midwives but by medical men, the charges would be made so high that poor people would not be able to pay for midwives.

The amendment was rejected by 19 votes to two.

Mr. Heywood Johnstone moved to insert "the local supervising authority may delegate, with or without any restrictions or conditions as they may think fit, any powers or duties conferred or imposed upon them by or in pursuance of this Act, to a committee appointed by them and consisting either wholly or partly of members of the council, and the provisions of sub-sections one and two of section 82 of the Local Government Act, 1888, shall apply to every committee appointed under this section and to every council appointing the same."

The hon. Member explained that this provision was taken from the Parish Councils Act of 1894. He had not specified any particular class of physicians or otherwise from whom the coöpted members might be drawn. He thought they could very safely leave that to the good judgment and discretion of the county councils who knew what material they had available for the work. The provisions mentioned in the latter part of the amendment had reference to machinery, the necessary quorum, place of meeting, chairman, and other details.

Mr. Parker Smith asked whether the provision would enable women to serve upon the committee.

The Solicitor-General (Sir Robert Finlay) said the point might be argued and therefore it would be better to put in express words.

The Committee agreed to insert "provided that women shall be eligible to serve upon such committees" and with this addition the amendment was adopted.

Colonel Milward suggested that some limit should be placed on the size of the committees.

Mr. Heywood Johnstone said he would not object to some limitation.

Sir Francis Powell thought it would be better to leave the limit to the discretion of the council.

The Committee endorsed this view.

Clause 10 proposed that a county council may delegate with or without any restrictions or conditions as they may think fit any powers or duties conferred or imposed upon them by or in pursuance of the Act to any district council within the area of the county.

On the motion of Mr. Heywood Johnstone it was agreed to add: "And the powers and duties so delegated may be exercised by a committee appointed by such district council and consisting either wholly or partly of members of the district council." And on the motion of the Solicitor-General to further add: "Any expenses incurred by a district council in the execution of any powers or duties so delegated shall, to an amount not exceeding such sum as may be prescribed by the county council, be repaid to such district council as a debt by the county council. Any excess above the sum so prescribed shall be borne by the district council as part of their ordinary expenses. The provisions of this section shall apply to the administrative county of London in like manner as if each metropolitan borough were a county district and the borough council were the district council of that district."

In Clause 11, dealing with the midwives' licence, amendments were made to provide that the licence shall run until the end of January, *giving the woman the whole month in which to take out the new* licence.

Clause 12, which provides penalties, was altered, and instead of making the offence of an unlicensed woman attending a patient a misdemeanour it was made a summary offence.

On the notice paper the following amendment stood opposite the *name of Sir George Pilkington, viz.*: "Any woman, whether certified or licensed under this Act or not, who after the first day of January, 1902, shall receive as a midwife, a pregnant or lying-in woman in premises which shall not have been certified by the Board as fit for the reception of such a woman under the provisions of this Act shall be guilty of a misdemeanour, and on conviction on indictment shall be liable at the discretion of the court to a fine not exceeding £10, or to imprisonment for any term not exceeding two months with or without hard labour, or to both fine and imprisonment, or, on summary conviction to a fine not exceeding £10."

Sir George Pilkington was not present and accordingly the amendment was passed over.

Clause 13, providing a penalty for wilful falsification of the roll, was agreed to without discussion, and Clause 14, which deals with the prosecution of offences, was amended in regard to certain details. The wording of Clause 15, giving an appeal to the Privy Council in case of disagreement between the General Medical Council and the Central Midwives Board, was also slightly amended, while Clause 16, "Nothing in this Act respecting midwives shall apply to legally qualified medical practitioners," was agreed to without debate.

On Clause 17, limiting the operation of the Act to England and providing that the General Medical Council shall act by the English Branch Council, which for all the purposes of the Act shall occupy the place of the General Medical Council,

Mr. Tennant advocated the extension of this legislation to Scotland and said the promoters should either amend the present Bill with this object or introduce a separate measure for Scotland.

Mr. Parker Smith, speaking in the same sense, said that this legislation was quite as much if not more needed in Scotland than in England.

Mr. Heywood Johnstone said that he thought Scotland would be better dealt with in another Bill. He only hoped that those who given such loyal help and assistance to this Bill would give the same to a Scottish Bill. It was really very much a question of machinery and they had not thought it desirable in this Bill to try to set up the machinery which they believed would be necessary for Scotland and which, to some extent at all events, would differ from the machinery for England. He therefore could not hold out any hopes of dealing with Scotland on the report stage of this Bill, though he desired very much to see a Bill on this subject dealing both with Scotland and Ireland and also the Isle of Man

The clause was then agreed to.

On the definition clause

Mr HEYWOOD JOHNSTONE moved to alter the definition of the term "midwife" so as to read "a woman who undertakes for reward to attend women in childbirth where no registered medical practitioner is engaged or employed" The effect of the amendment, he said, would be broadly to define women who attended child birth into two classes—those who attended under the superintendence and regulation of a registered medical practitioner and those who attended without such superintendence and regulation The women whose training they wished to ensure and whose practice to regulate were the latter This definition would make it perfectly clear that they did not intend to interfere in any way with the monthly nurse who was engaged with a doctor to attend to a lying in woman

The amendment was agreed to by the Committee.

The next notice on the paper was an amendment in the name of Sir George Pilkington to make the definition read "The term 'midwife' means a woman who undertakes for gain and in accordance with the provisions of this Act to attend women in natural labour but not in cases which present difficulty, abnormality, danger, or disease on the part of the mother or the new born child"

Mr VICARY GIBBS said he had promised to move this amendment but he had not promised to present arguments in its favour Indeed, he believed this amendment would wreck the Bill and make it absolutely worthless

The CHAIRMAN ruled that the amendment was out of order after what had been accepted by the Committee

Clause 13 was then agreed to

The Committee reverted to Clause 6, which was in the following terms viz :—

1 A county council shall be empowered to pay out of the county funds as general expenses incurred by them in the execution of their duties under the Local Government Act, 1888, any sum from time to time required to make good a deficiency in the funds of the Central Midwives Board

2 Such expenses as the Treasury may certify to have been necessarily incurred by the General Medical Council in the execution of this Act shall be defrayed out of moneys provided by Parliament

The CHAIRMAN said that the only part of this clause which came before the Committee was the first sub-section, the financial resolution with regard to the second sub-section not having been passed by the House

On the motion of the SOLICITOR-GENERAL the first sub-section was struck out of the Bill

A clause in these terms, "Any expenses under this Act payable by the council of a county or county borough shall be defrayed out of the county fund or out of the borough fund or borough rate, as the case may be," was on the motion of the SOLICITOR-GENERAL, inserted in the Bill.

Three other new clauses were on the notice paper, but none of them were moved and the Bill was ordered for report to the House of Commons

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, for publication in the next number.*

AINSWORTH H P, L.R.C.P. Lond., M R.C.S, has been appointed Medical Officer for the Fourth Sanitary District of the North Witchford Union, vice G P O'Connor, resigned

BARON, H N, L.R.C.P Lond, M R C S, has been appointed Medical Officer for the Orford Sanitary District of the Plomesgate Union vice F S Flint, deceased

BEVERIDGE, A. T G, M B, C M Aberd, has been re-appointed Medical Officer, Aberdeen General Dispensary

BOND, FRANCIS THOMAS M D Lond, M R.C S, F R S Edin., has been re appointed Medical Officer of Health for the Cirencester Rural District Council

BRADBURNE, ARTHUR A., L.R.C.P & S Edin., L.F P.S Glasg., late House Surgeon at Teignmouth Hospital, has accepted an appointment under the War Office at Connaught Hospital, Aldershot

BROADBENT, GEO, L.R C P, L.R C S Edin, L.F P S Glasg, has been appointed Medical Officer for the Maltby Sanitary District of the Rotherham Union, vice W H Crossley, deceased.

CLARKE, ARTHUR EDWARD, M.B Lond, M.R C S, L.R.C P, has been appointed House Physician to Guy's Hospital, London

COOPER, C E. M B., B C Cantab., has been appointed Certifying Surgeon under the Factory Acts, for the Urban District of Ivybridge, the Civil Parish of Ugborough in Totnes Rural District, and the Civil Parishes of Cornwood, Harford, and Ermington, in Plympton St Mary Rural District.

DALGARNO, J J Y, M.B., C M Aberd., has been re-appointed Medical Officer, Aberdeen General Dispensary

DAVIES, AUBREY H, B A. Cantab., M R.C S, L.R C P, has been appointed Assistant House Surgeon to Guy's Hospital, London

York County Hospital.—House Surgeon. Salary £80 per annum, with board, residence, and washing.

Births, Marriages, and Deaths.

BIRTHS.

Best.—On March 18th, at Waltham-cross, Herts, the wife of F. H. de Greaves Best, M.R.C.S., L.R.C.P., of a son.

Collins.—On March 21st, at Ulverston, Lancashire, the wife of A. W. Collins, M.B., D.P.H., of a daughter.

Eccles.—On March 24th, at Harley-street, W., the wife of W. McAdam Eccles, M.S. Lond., F.R.C.S. Eng., of a daughter.

Glasson.—On March 25th, at Cardigan House, Chadwell Heath, Essex, the wife of C. J. Glasson, M.D., of a son.

Howitt.—On March 26th, at Ebor House, Grove-park, Chiswick, the wife of G. G. Howitt, M.D., of a son.

Sutcliff.—On March 19th, at Great Torrington, Devon, the wife of Harvey Sutcliff, M.B., M.R.C.S., of a daughter.

Sylvester.—On March 23rd, at Leiston, Suffolk, the wife of Herbert Mayris Sylvester, M.R.C.S., L.R.C.P. Lond., of a daughter.

Tyson.—On March 23rd, at Lowestoft, the wife of Wilson Tyson, M.A., M.B., B.C. Cantab., of a daughter.

Whitcombe.—On March 26th, at 164, Earl's Court-road, Kensington, the wife of P. P. Whitcombe, M.B. Lond., of a son.

DEATHS.

Bayley.—On March 23rd, at Priory Cottage, Northampton, Cecil Bayley, L.R.C.S., L.R.C.P. Edin., aged 31 years.

Fyfe. On March 26th, at Ealing, Andrew Fyfe, M.D., F.R.C.S. Edin., aged 72 years.

Gunning.—On March 22nd, at Addison-crescent, Kensington, Robert Halliday Gunning, M.D., LL.D., aged 81 years.

King.—On March 16th, at Whitstable, Kent, Henry Stavely King, M.D. Lond., M.A. Cantab, aged 68 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths

Notes, Short Comments, and Answers to Correspondents.

THE REGISTERED QUACK

THE ordinary quack undertakes to treat diseases about which he knows absolutely nothing But at all events he has not been admitted into a brotherhood of men membership of which entails great responsibilities and the presumption of possessing an amount of knowledge which has been keenly tested When a qualified and registered medical man does go wrong—and fortunately such instances are rare—he goes very wrong indeed He has nerve and he has knowledge. For this reason we desire to call the attention of the medical profession, to say nothing of the General Medical Council, to an advertisement of the most shameless character which appears in the *Queensland Times* for Jan 25th, 1900 The advertisement in question is on page 6 and occupies the top half of the left hand column. We reproduce it as it stands, with the exception of the embellishment of "Dr." Tarrant's portrait.

Dr. Tarrant,

F.R C.S E., L.R C P E, L M.R C P.E., ALSO
L R C S I,

FOR sixteen years Hon Surgeon to the Sydney Hospital—Registered by the GOVERNMENT Medical Board—has during his recent world wide travels discovered a

New Method of Healing,

which acts like Magic in removing Foul Breath Indigestion, Palpitation, Blushing, Shortness of Breath, Impaired Memory, Weak, Sore, Sunken, or Dark Circled Eyes, Sallow or Pimply Skin, Dulness of Intellect, Piles, Constipation or Relaxation of the Bowels, Bad Taste, Wind, Desire for Solitude or Drink, Bashfulness, Weak Back, Bad Feet, Oozing of Saliva from the Mouth during Sleep, Neuralgia, Hacking Cough, Giddiness, Fear of Insanity or Suicide, Inclination to throw yourself down when over water, Inability to keep your Thoughts off Impure Subjects Dreams, Twitching of the Eye lids, Numbness or Prickly Sensations, Timidity, Fear of Impending Danger, &c.

Dr TARRANT makes *absolutely no charge* for Advice—but £1 is required to cure almost any complaint, including Skin Diseases, Liver Troubles, Gravel, Scrofula, Throat, Eye, or Ear Complaints, Fistula, Piles, Paralysis, Sciatica, Rheumatism, Constipation, Hip Disease, Dropsy, Worms, Epilepsy (Fits), Bright's Disease, Influenza, Lung Troubles, Coughs, Neuralgia, Varicocele, &c

You should, to avoid delay, enclose £1 in First Letter If Dr TARRANT decides that he cannot cure you, *the pound will be returned to you.*

All communications should be addressed to

DR. HARMAN TARRANT,
151, ELIZABETH STREET, SYDNEY,

Or, if preferred, H T, Box 1204, G P O, Sydney.—

If you desire full information re All Complaints, or if it is your intention to Marry send 6d in Stamps for Dr TARRANT'S Exhaustive Work. This beautiful volume will be found to contain 125 prescriptions for self-cure, many appropriate illustrations, and is entitled

"Independence of the Healthy."

(Please mention "Queensland Times" when writing)

Now we have no hesitation in saying that this advertisement is one of the most pestilential we have seen and the worst part of the matter is that "Dr" Harman Tarrant's name appears in the Medical Register for 1899 as Tarrant, Harman John, Sydney, New South Wales, 1867, Oct. 21st, E, Lic R Coll Surg Irel, 1867, Lic. R Coll. Phys Edin 1867, Fell. R. Coll Surg Edin, 1837 Mr Tarrant's name should at once be removed from the Medical Register and we trust that the bodies which gave him his diplomas will also take some notice of his behaviour

Mr Tarrant's effusion also appears in the *Sunday Times* of Sydney of Feb. 11th, 1900, in company with a number of other advertisements of the same kidney One of these is headed: "Dr Gibbons, M A., L.R C P E, L.R C S E, L.M R C E, ETC" "Dr" Gibbons describes himself as being trebly qualified and registered in London and the colonies as a physician and surgeon He also says that he has made a life-long study of private diseases Unlike Tarrant, Gibbons does not say anything about no charge for advice but modestly intimates that £1 is sufficient to send *Gibbons does not* give his initials so we are unable to confirm his statement that he is registered as a physician and surgeon in London In the Medical Register for 1899 there is no Gibbons in the Colonial List, but on page 632 there are seven gentlemen bearing the name of Gibbons Only two of these, however, register an Edinburgh degree or diploma and they are respectively an M D and an M B of the University of Edinburgh. Obviously neither of these gentlemen is the person upon whom we are animadverting Perhaps the General Medical Council will take note of Gibbons's assumption

THE PARIS MUNICIPALITY AND THE SPREAD OF INFECTION

To the Editors of THE LANCET

SIRS,—On Friday, March 16th, a by law was passed by the Paris Municipal Council against spitting in public places, including, as I understand, the streets of the city From an æsthetic point of view their action is beyond cavil. Their intention, however, as judged by the speech of M Fortin, who moved the resolution, was the suppression of contagium To me it seems the converse will result for the following reasons *Sunlight* and *fresh air have a powerful bactericidal* action, so much so that the tubercle bacillus is destroyed when exposed to both in from eight to 12 hours I believe I am correct in stating so is also the Klebs Löffler and, in fact, the majority of micro organisms Again, dilution, such as would of necessity exist in open places, attenuates contagium Persons who suffer from chest and throat affections must expectorate What, then, will be the result? They will spit into their handkerchiefs, those will go into the soiled clothes basket swarming with micro-organisms, which, *in the heated air of the house, will rapidly desiccate* We have, as a consequence, a concentrated contagium in a confined space

I am, Sirs, yours faithfully,

Ballincollig, March 22nd, 1900 JAMES J HARDING, D P H, &c

To the Editors of THE LANCET.

SIRS,—The recent enactment of the Paris Municipal Council against street-spitting should at least awaken consideration of the subject by our own London County Council I should imagine in the case of a similar prohibition (as obtains in the *United States and Paris) being* adopted the district of Spitalfields should be exempt and the attention of the officers of the Sal(i)vation Army called to the matter How the London County Council can ever hope to expect-a rate should they be compelled to pass a by law against spitting in the streets seems a puzzle to me.

I am, Sirs, yours faithfully,

Cheltenham, March 26th, 1900, ALEXANDER DUKE.

SURGERY IN FICTION.

TRUTH, it is often said, and *rightly so, is stranger than fiction* The astounding cases of recovery after injury to what are commonly supposed to be vital portions of the economy which have been reported from time to time in our columns in the graphic letters supplied to us from the front by Sir William MacCormac are sufficiently remarkable, but even they must pale before the quotation from a popular novel which is given in the following letter *from* a correspondent —

To the Editors of THE LANCET.

SIRS,—The astonishing skill and profound knowledge of the "doctor" of fiction are well known. As you have occasionally amused your readers with extracts illustrating the above I think the following from a work by a well known novelist may interest you The hero is accidentally run through the "chest' by a foil the button of which had become detached The "medical practitioner of the district' is on the spot and pronounces the wound as dangerous but not necessarily fatal. Later, however, "he will by no means commit himself to a definite opinion' as to *prognosis* and *delivers the following* opinion:—"Without a doubt it was a critical case. Though the cœliac axis had been missed by a miracle the vasa vasorum blood vessel had suffered lesion The left sub-clavian artery had been torn through, yet from its known power of contraction he trusted that the interior lining would be closed, when further loss of blood would cease Of course unfavourable symptoms might supervene at any moment—at any moment Quiet—that is absolute rest—was indispensable With no exciting visits, and—yes—with the closest attention and *good nursing*, a distinctly favourable termination might be—ahem—hoped for" You will be glad to hear, however, that despite the above formidable injuries in the course of a week the popular practitioner alluded to had the honour of informing the anxious inhabitants of the surrounding district that the injury having, as he had the honour to diagnose, "providentially not occurred to the trunk artery the middle coat of the smaller blood vessel had, from its elastic and contractile nature, after being torn by the partially blunted end of the foil, caused a closure In point *of fact*, the injury had yielded to treatment. He would definitely pledge himself, in fact, that the patient was bordering upon convalescence. In a week or two he would be ready to support a removal, &c., when doubtless his youth, temperate habits and excellent constitution would combine to produce a complete recovery' The above is apparently written in all seriousness and the author is, as I have said, one who has achieved *for* himself a considerable reputation

I am, Sirs, yours faithfully,

W. G A.

CONFLICTING MEDICAL EVIDENCE: A VERY PROPER VERDICT.

AN inquest was held on March 20th concerning the cause of the death of a man named William Tabern Up to Nov 14th, 1899, Tabern had worked at the White Cross Collieries On that day his back and leg were hurt by a stone falling upon them He did not go to work again and stayed for a month in bed Dr E P Twyford said that from Feb 27th to March 5th 1900, he had seen Tabern daily. He had made a post-mortem examination and had found excessive degeneration of the arteries of the brain. Mr. P. J. O'Keeffe was present at the post-mortem examination. Dr. Twyford gave it as his opinion that the man died from natural causes—i.e., disease of the brain. Mr. O'Keeffe said that in his opinion death was caused by an accident. Tabern had worried a great deal after his accident lest he should not be able to get work again after his recovery. He would have lived longer if the accident had not occurred. A majority of the jury returned a verdict that the deceased died from the accident. The coroner, however, said that he must have a unanimous verdict. The inquiry was adjourned. At the resumption on March 21st further medical evidence was given by Mr. Turner, Dr. Twyford's assistant, and Dr. Robert Jackson. Both were of opinion that death was due to degeneration of the cerebral arteries and that the accident had in no way hastened death. Mr. O'Keeffe repeated that he considered that the injury was the indirect cause of the man's death. The jury eventually returned an open verdict, stating that they were unable to say whether the degenerative changes in the brain were the result of the accident or not. The coroner said that he quite agreed with the verdict.

"UNUSUAL ENDING OF A CASE OF EMPYEMA."

To the Editors of THE LANCET.

SIRS,—The following case may prove of interest in relation to Dr. Cropper's case published in THE LANCET of March 17th. In December, 1896, a friend of mine in Salford had a case of pneumonia in a girl, aged 19 years. The doctor died shortly after, and a gentleman who acted as "locum" till the widow could make arrangements asked me to go with him to see the above patient. We found the whole of the left side dull, also an emphysematous area of about two and a half inches in diameter, so far as I recollect, above the left breast. She was coughing up fœtid pus and was vomiting it also, but the quantity vomited was much greater than that expectorated. A few days after I removed a portion of rib and drained. The girl made a good though rather tedious recovery, with much less deformity than we had expected. Was the vomited pus first coughed up and swallowed or was there an opening from the pleura into the stomach or the œsophagus? I think the quantity vomited favours the latter view. I should be glad of the opinions of others on this case.

I am, Sirs, yours faithfully,

Great Moor, Stockport, March 22nd, 1900. W. R. MANDER.

*** Perforation into the œsophagus is probably what occurred.—ED. L.

SUCCESSFUL ACTION BY A MEDICAL MAN.

AN action was recently tried in the Tunbridge Wells County Court wherein Mr. W. Stamford, M.R.C.S. Eng., sued Mr. Hammond, a local builder, for the sum of £31 8s. 6*d.* for medical attendance. Mr. Stamford gave evidence that he had attended defendant for a long time. Mr. Robb, a solicitor, who appeared for Mr. Hammond, argued that the charges were excessive and that defendant was only a working bricklayer. Dr. J. E. Ranking, the senior physician at the Tunbridge Wells Hospital, said he knew the case of Mr. Hammond well. It was a serious and prolonged case and the fees were justifiable. Defendant was ordered to pay the amount claimed and costs, on which we congratulate Mr. Stamford.

A QUESTION OF SALARY.

To the Editors of THE LANCET.

SIRS,—A practitioner for whom I acted as locum tenens paid me at the rate of £3 3s. per week, stating that he had agreed upon those terms with the chemists from whom he got my name. I told him that my fee was £4 4s. per week. On subsequent inquiry from the chemists I found that no mention had been made of terms. Am I entitled to the balance of my fee and, if so, what steps should I take to recover it? I have already written to the principal stating my claim.

I am, Sirs, yours faithfully,

March 20th, 1900. C.M., M.B.

*** If "C.M., M.B." agreed to give his services for £3 3s. per week he must abide by his bargain. But if the principal obtained those services for £1 1s. a week less than he could otherwise have obtained them for by making an inaccurate statement, we think the principal should not keep "C.M., M.B." to the bargain, but should pay him on the higher scale.—ED. L.

"THE ROYAL NAVY MEDICAL DEPARTMENT."

To the Editors of THE LANCET.

SIRS,—My attention has been called to a letter in THE LANCET of March 24th, where on p. 899 a correspondent refers to the inspection by the General Medical Council of certain university examinations for the M.B. degree. He is exercised to find that the Medical Department of the Admiralty signalises in the Navy List the holders of degrees and withholds any other qualifications held by non-graduates. He seeks to belittle the value of the M.B. degree by reference to a report of the Visitor and Inspectors of the Medical Council on two of the universities, part of which he quotes. The date of that report is 1885. Since that time—viz., in 1892—these universities, together with all others in the three kingdoms, have been again visited and inspected by the Medical Council and in common fairness your correspondent should have quoted from these, the last, reports. A reference to vol. xxx., 1893, of the Council's Minutes will satisfy him, and all others concerned, that the examinations he refers to were found to be sufficient and satisfactory. It forms no part of the duty of the General Medical Council to indicate whether any examination held by universities or corporations is superior or inferior to another. Its statutory duty is merely to declare whether these examinations are "sufficient" within the meaning of the Medical Act. I will venture lastly to state my belief that the Medical Department of the Admiralty well understands its own business.

I am, Sirs, yours faithfully,

DYCE DUCKWORTH,

Chairman of the Examination Committee

March 26th, 1900. of the General Medical Council.

DRUGS WHICH COLOUR THE URINE.

To the Editors of THE LANCET.

SIRS,—I should feel obliged if you could tell me through THE LANCET what are the different drugs which colour urine, also the names of any books giving information on the subject.

I am, Sirs, your faithfully,

March 23rd, 1900. STUDENT.

*** Rhubarb and santonin colour the urine yellow, but if the urine be very alkaline santonin colours it red. Carbolic acid, impure salicylates, and creasote give a blackish-green colour and methylene blue colours the urine blue, senna gives it a brown colour, and hæmatoxylin a reddish tinge. Information may be found in various books upon clinical diagnosis.—ED. L.

TO MEDICAL FREEMASONS.

To the Editors of THE LANCET.

SIRS,—May I, through your columns, ask my Masonic brethren—more especially old King's men—for any votes they can possibly spare or obtain on behalf of the little son of the late F. W. Skrimshire (an obituary notice of whom appeared in THE LANCET of Dec. 2nd, 1899) who is a candidate for the Boys' School at the coming April election, and, I believe, the only one from our profession. They will be most gratefully received either by the widow, Mrs. Skrimshire, 2, Southampton-terrace, Farnborough, Hants, or by

Yours faithfully,

GEO. JNO. EADY.

Juglans Lodge, Enfield, Middlesex, March 27th, 1900.

"A SAD AND URGENT CASE."

To the Editors of THE LANCET.

SIRS,—The following are the subscriptions received since the last notified and which now close the list, the total amount subscribed in response to Dr. Macnaughton Jones's appeal being £110 5s. 6*d.* I enclose a copy of receipt from the solicitor who has kindly undertaken the further disbursement of the fund in weekly payments.

I remain, Sirs, faithfully yours,

WILLIAM H. BOURKE, M.D. Brux.

South Kensington, March 28th, 1900.

Mr. A. Cosgrave	1	1	0				

[COPY.]

Carlton Chambers, 8, Regent-street, S.W., Feb. 26th, 1900.

SAD AND URGENT CASE.

Received from Dr. W. H. Bourke, the Treasurer of this Fund, the sum of eighty-two pounds nineteen shillings and tenpence, being the balance in his hands (after certain urgent payments), to be applied by me as arranged for the benefit of the recipient and his family. HERBERT R. BLISS, Solicitor.

ENGLISH PRACTITIONERS IN SPAIN.

A CORRESPONDENT would be glad to know what restrictions, if any, govern the practice in Spain of medical men holding English qualifications.

◆

Surgeon.—The debt ought to be recovered by legal process in the county court. The circumstances are such that if they are properly supported by evidence the debtor will obtain no sympathy from the judge. We do not think any criminal proceedings are indicated, and are very doubtful if such could be taken; but of course our correspondent will only act under legal advice.

W. S.—We agree with much of our correspondent's letter, but we cannot advocate the giving of heroic doses of dangerous drugs. The dosage of the Pharmacopœia is based upon the experience of many medical men carefully verified and collated, and the medical man who administers a dose four times as large as the official one takes upon himself a dangerous responsibility.

Medicus.—We are not aware that the paper is supplied through us. Our correspondent should consult his newsagent. We have not the information asked for concerning the *Biographer*, but we advise "Medicus" not to give the information asked for and not to send money.

Inquirer.—The purchase price is usually calculated upon gross receipts.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

ROYAL INSTITUTION OF GREAT BRITAIN.—9 P.M. Prof. Dewar: Solid Hydrogen.

EDITORIAL NOTICES.

It is most important that communications relating to the Editorial business of THE LANCET should be addressed exclusively "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

Communications, Letters, &c., have been received from—

A.—Dr. C. M. Allan, Longton; Messrs. Allen and Hanburys, Lond.; Dr. Adamson, Hetton-le-Hole; A. D. H.
